#### Abstract

We studied the association between SEP events during 1977-2003 and related CMEs and found each GLE event was associated with a primary CME, which was faster (average speed $\sim 1762 \mathrm{~km} \cdot \mathrm{~s}^{-1}$ ) and wider (average angle width of $317^{0}$ ) than an average CME . All SEP-related CMEs distributed within solar source regions of latitude strip of $\mathrm{S} 30^{\circ}-\mathrm{N} 40^{\circ}$, while $11(85 \%)$ GLE-related CMEs originated from the western hemisphere. These fast halo CMEs ( $75 \%$ full-halo and $25 \%$ partial-halo) were associated with type II radio bursts in the decameter hectometer ( DH ) wavelengths.

Keywords. Sun: coronal mass ejections (CMEs), particle emission, radio radiation

## 1. Observation

Large solar energetic particles (SEPs) are thought to be accelerated by CMEs-driven shocks (see, e.g., Reames, 1999; Kahler, 2001). Nevertheless, It is still not known what makes a CME an SEP accelerator, especially for those largest SEPs or GLEs. In this paper we study the CMEs associated with SEP events which are divided three classes, the $13 \mathrm{GLE}, 30$ moderate $\operatorname{SEP}(10-100 \mathrm{pfu}, \mathrm{E}>10 \mathrm{MeV})$ and 62 minor $\mathrm{SEP}(1-10 \mathrm{pfu}$, $\mathrm{E}>10 \mathrm{MeV}$ ) during 1997-2003. Using Data are from SOHO/LASCO, SGD, EIT, SXT and GOES, we identified related CMEs and flares and collected their measured properties. CMEs and flares correlated with 13 GLEs were listed in table 1. The columns from left to right represent GLE date, peak flux time of x-ray flare, optical flare class, peak flux of SEPs with energies above 10 MeV , onset time, angular width (AW) and velocity of CME, heliocentric coordinates of solar source, NOAA active region number. Whether associated or not a decameter hectometer (DH) type II burst ("y" for yes and "n" for no). Solar surface source region distribution was plotted in figure 1 and the speed distribution of three classes of CMEs was plotted in figure 2.

## 2. Results

Main results of this study are: (1) Each GLE event corresponds a fast halo CME, including 9 ( $75 \%$ ) full-halo CMEs and 3 ( $25 \%$ ) partial-halo CMEs. (2) 9 GLEs ( $69 \%$ ) originated from the southern hemisphere and 11 GLEs ( $85 \%$ ) originated from the western hemisphere. Latitude of the solar source region is within a strip of $330^{0}-\mathrm{N} 40^{0}$. Longitude of GLE-CMEs is west of $\mathrm{E} 10^{\circ}$ with the most probable longitude of between W60 ${ }^{\circ}$ and W70 ${ }^{0}$. (3) The CME average speeds are $\sim 1762 \mathrm{~km} \cdot s^{-1}, \sim 1077 \mathrm{~km} \cdot s^{-1}$ and $\sim 887$ $\mathrm{km} \cdot s^{-1}$ respectively for the GLE-CMEs, the moderate SEP-CMEs and the minor SEPCMEs. There are 11 (92\%) GLE-CMEs whose speed exceeding $1000 \mathrm{~km} \cdot \mathrm{~s}^{-1}$. (4) Of the 13 GLE related flares, 11 (85\%) were class x level. SEP fluxes exceeded several hundreds
