# Tangent cones to generalised theta divisors and generic injectivity of the theta map 

George H. Hitching and Michael Hoff

#### Abstract

Let $C$ be a Petri general curve of genus $g$ and $E$ a general stable vector bundle of rank $r$ and slope $g-1$ over $C$ with $h^{0}(C, E)=r+1$. For $g \geqslant(2 r+2)(2 r+1)$, we show how the bundle $E$ can be recovered from the tangent cone to the generalised theta divisor $\Theta_{E}$ at $\mathcal{O}_{C}$. We use this to give a constructive proof and a sharpening of Brivio and Verra's theorem that the theta map $S U_{C}(r) \rightarrow|r \Theta|$ is generically injective for large values of $g$.

## 1. Introduction

Let $C$ be a nonhyperelliptic curve of genus $g$ and $L \in \operatorname{Pic}^{g-1}(C)$ a line bundle with $h^{0}(C, L)=2$ corresponding to a general double point of the Riemann theta divisor $\Theta$. It is well known that the projectivised tangent cone to $\Theta$ at $L$ is a quadric hypersurface $R_{L}$ of rank less than or equal to 4 in the canonical space $\left|K_{C}\right|^{*}$, which contains the canonically embedded curve.

Quadrics arising from tangent cones in this way have been much studied: Green [Gre84] showed that the $R_{L}$ span the space of all quadrics in $\left|K_{C}\right|^{*}$ containing $C$; and both Kempf and Schreyer [KS88] and Ciliberto and Sernesi [CS92] have used the quadrics $R_{L}$ in various ways to give new proofs of Torelli's theorem.

In another direction: via the Riemann-Kempf singularity theorem [Kem73], one sees that the rulings on $R_{L}$ cut out the linear series $|L|$ and $\left|K_{C} L^{-1}\right|$ on the canonical curve. Thus the data of the tangent cone and the canonical curve allow one to reconstruct the line bundle $L$. In this paper we study a related construction for vector bundles of higher rank.

Let $V \rightarrow C$ be a semistable vector bundle of rank $r$ and integral slope $h$. We consider the set

$$
\begin{equation*}
\left\{M \in \operatorname{Pic}^{g-1-h}(C): h^{0}(C, V \otimes M) \geqslant 1\right\} \tag{1}
\end{equation*}
$$

It is by now well known that for general $V$, this is the support of a divisor $\Theta_{V}$ algebraically equivalent to a translate of $r \cdot \Theta$. If $V$ has trivial determinant, then in fact $\Theta_{V}$, when it exists, belongs to $|r \Theta|$.

For general $V$, the projectivised tangent cone $\mathcal{T}_{M}\left(\Theta_{V}\right)$ to $\Theta_{V}$ at a point $M$ of multiplicity $r+1$ is a determinantal hypersurface of degree $r+1$ in $\left|K_{C}\right|^{*}$ (see, for example, Casalaina-Martin and Teixidor i Bigas [CT11]). Our first main result (§3.2) is a construction which from $\mathcal{T}_{M}\left(\Theta_{V}\right)$

[^0]
## G. H. Hitching and M. Hoff

recovers the bundle $V \otimes M$, up to the involution $V \otimes M \mapsto K_{C} \otimes M^{-1} \otimes V^{*}$. This is valid whenever $V \otimes M$ and $K_{C} \otimes M^{-1} \otimes V^{*}$ are globally generated.

We apply this construction to give an improvement of a result of Brivio and Verra [BV12]. To describe this application, we need to recall some more objects. Write $S U_{C}(r)$ for the moduli space of semistable bundles of rank $r$ and trivial determinant over $C$. The association $V \mapsto \Theta_{V}$ defines a map

$$
\begin{equation*}
\mathcal{D}: S U_{C}(r) \rightarrow|r \Theta|=\mathbb{P}^{r^{g}-1} \tag{2}
\end{equation*}
$$

called the theta map. Drezet and Narasimhan [DN89] showed that the line bundle associated to the theta map is the ample generator of the Picard group of $S U_{C}(r)$. Moreover, the indeterminacy locus of $\mathcal{D}$ consists of those bundles $V \in S U_{C}(r)$ for which (1) is the whole Picard variety. This has been much studied; see, for example, Pauly [Pau10], Popa [Pop99] and Raynaud [Ray82].

Brivio and Verra [BV12] showed that $\mathcal{D}$ is generically injective for a general curve of genus $g \geqslant\binom{ 3 r}{r}-2 r-1$, partially answering a conjecture of Beauville [Bea06, §6]. We apply the aforementioned construction to give the following sharpening of Brivio and Verra's result.

Theorem 1.1. For $r \geqslant 2$ and $C$ a Petri general curve of genus $g \geqslant(2 r+2)(2 r+1)$, the theta map (2) is generically injective.

In addition to giving the statement for several new values of $g$ when $r \geqslant 3$ (our lower bound for $g$ depends quadratically on $r$ rather than exponentially), our proof is constructive, based on the method mentioned above for explicitly recovering the bundle $V$ from the tangent cone to the theta divisor at a point of multiplicity $r+1$. This gives a new example, in the context of vector bundles, of the principle apparent in [KS88] and [CS92] that the geometry of a theta divisor at a sufficiently singular point can encode essentially all the information of the bundle and/or the curve.

Our method works for $r=2$, but in this case much more is already known: Narasimhan and Ramanan [NR69] showed, for $g=2$ and $r=2$, that $\mathcal{D}$ is an isomorphism $S U_{C}(2) \xrightarrow{\sim} \mathbb{P}^{3}$, and van Geemen and Izadi [vGI01] generalised this statement to nonhyperelliptic curves of higher genus. Note that our proof of Theorem 4.1 is not valid for hyperelliptic curves (see Remark 4.3).

Here is a more detailed summary of the paper. In $\S 2$, we study semistable bundles $E$ of slope $g-1$ for which the Petri trace map

$$
\bar{\mu}: H^{0}(C, E) \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow H^{0}\left(C, K_{C}\right)
$$

is injective. A bundle $E$ with this property will be called Petri trace injective. We prove that for large enough genus, the theta divisor of a generic $V \in S U_{C}(r)$ contains a point $M$ of multiplicity $r+1$ such that $V \otimes M$ and $K_{C} \otimes M^{-1} \otimes V^{*}$ are Petri trace injective and globally generated.

Now suppose that $E$ is a vector bundle of slope $g-1$ with $h^{0}(C, E) \geqslant r+1$. If $\Theta_{E}$ is defined, then the tangent cone to $\Theta_{E}$ at $\mathcal{O}_{C}$ is a determinantal hypersurface in $\left|K_{C}\right|^{*}=\mathbb{P}^{g-1}$ containing the canonical embedding of $C$. We prove (Proposition 3.3 and Corollary 3.5) that if $C$ is a general curve of genus $g \geqslant(2 r+2)(2 r+1)$, and $E$ a globally generated Petri trace injective bundle of rank $r$ and slope $g-1$ with $h^{0}(C, E)=r+1$, then the bundle $E$ can be reconstructed up to the involution $E \mapsto K_{C} \otimes E^{*}$ from a certain determinantal representation of the tangent cone to $\Theta_{E}$ at $\mathcal{O}_{C}$. By a classical result of Frobenius (whose proof we sketch in Proposition 3.7), any two such representations are equivalent up to transpose. The generic injectivity of the theta map for a Petri general curve (Theorem 4.1) can then be deduced by combining these facts and the statement in $\S 2$ that the theta divisor of a general $V \in S U_{C}(r)$ contains a suitable point of multiplicity $r+1$.

## GENERIC InJECTIVITY OF THE THETA MAP

We assume throughout that the ground field is $\mathbb{C}$. The reconstruction of $E$ from its tangent cone in $\S 3.2$ is valid for an algebraically closed field of characteristic zero or $p>0$ not dividing $r+1$.

## 2. Singularities of theta divisors of vector bundles

### 2.1 Petri trace injective bundles

Let $C$ be a projective smooth curve of genus $g \geqslant 2$. Let $V \rightarrow C$ be a stable vector bundle of rank $r \geqslant 2$ and integral slope $h$, and consider the locus

$$
\begin{equation*}
\left\{M \in \operatorname{Pic}^{g-1-h}(C): h^{0}(C, V \otimes M) \geqslant 1\right\} . \tag{3}
\end{equation*}
$$

If this is not the whole of $\operatorname{Pic}^{g-1-h}(C)$, then it is the support of the theta divisor $\Theta_{V}$.
The theta divisor of a vector bundle is a special case of a twisted Brill-Noether locus

$$
\begin{equation*}
B_{1, g-1-h}^{n}(V):=\left\{M \in \operatorname{Pic}^{g-1-h}(C): h^{0}(C, V \otimes M) \geqslant n\right\} . \tag{4}
\end{equation*}
$$

The following is central in the study of these loci (see, for example, Teixidor i Bigas [TiB14, § 1]): For $E \rightarrow C$ a stable vector bundle, we consider the Petri trace map:

$$
\begin{equation*}
\bar{\mu}: H^{0}(C, E) \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \xrightarrow{\mu} H^{0}\left(C, K_{C} \otimes \operatorname{End} E\right) \xrightarrow{\operatorname{tr}} H^{0}\left(C, K_{C}\right) . \tag{5}
\end{equation*}
$$

Then for $E=V \otimes M$ and $M \in B_{1, g-1-h}^{n}(V) \backslash B_{1, g-1-h}^{n+1}(V)$, the Zariski tangent space to the twisted Brill-Noether locus $B_{1, g-1-h}^{n}(V)$ at $M$ is exactly $\operatorname{Im}(\bar{\mu})^{\perp}$. This motivates the following definition.

Definition 2.1. Suppose $E \rightarrow C$ is a vector bundle with $h^{0}(C, E)=n \geqslant 1$. If the map $\mu$ above is injective, we will say that $E$ is Petri injective. If the composed map $\bar{\mu}$ is injective, we will say that $E$ is Petri trace injective.

Remark 2.2. (1) Clearly, a Petri trace injective bundle is Petri injective. For line bundles, the two notions coincide.
(2) Suppose $V \in U_{C}(r, d)$ where $U_{C}(r, d)$ is the moduli space of semistable rank $r$ vector bundles of degree $d$. If $E=V \otimes M$ is Petri trace injective for $M \in \operatorname{Pic}^{e}(C)$, then $B_{1, e}^{n}(V)$ is smooth at $M$ and of the expected dimension

$$
h^{1}\left(C, \mathcal{O}_{C}\right)-h^{0}(C, V \otimes M) \cdot h^{1}(C, V \otimes M)
$$

(3) We will also need to refer to the usual generalised Brill-Noether locus

$$
B_{r, d}^{n}=\left\{E \in U_{C}(r, d): h^{0}(C, E) \geqslant n\right\} .
$$

If $E$ is Petri injective then this is smooth and of the expected dimension

$$
h^{1}(C, \operatorname{End} E)-h^{0}(C, E) \cdot h^{1}(C, E)
$$

at $E$. See, for example, Grzegorczyk and Teixidor i Bigas [GT09, § 2].
(4) Petri injectivity and Petri trace injectivity are open conditions on families of bundles $\mathcal{E} \rightarrow C \times B$ with $h^{0}\left(C, \mathcal{E}_{b}\right)$ constant. Later, we will discuss the sense in which these properties are 'open' when $h^{0}\left(C, \mathcal{E}_{b}\right)$ may vary.

## G. H. Hitching and M. Hoff

We will also need the notion of a Petri general curve.
Definition 2.3. A curve $C$ is called Petri general if every line bundle on $C$ is Petri injective.
By [Gie82], the locus of curves which are not Petri general is a proper subset of the moduli space $M_{g}$ of curves of genus $g$, the so-called Gieseker-Petri locus. The hyperelliptic locus is contained in the Gieseker-Petri locus. Apart from this, in general not much is known about the components of the Gieseker-Petri locus and their dimensions. For an overview of known results, we refer to [TiB88, Far05, BS11] and the references cited therein.

Proposition 2.4. Suppose $V$ is a stable bundle of rank $r$ and integral slope $h$. Suppose $M_{0} \in \operatorname{Pic}^{g-1-h}(C)$ satisfies $h^{0}\left(C, V \otimes M_{0}\right) \geqslant 1$, and furthermore that $V \otimes M_{0}$ is Petri trace injective. Then the theta divisor $\Theta_{V} \subset \operatorname{Pic}^{g-1-h}(C)$ is defined. Furthermore, we have equality $\operatorname{mult}_{M_{0}} \Theta_{V}=h^{0}\left(C, V \otimes M_{0}\right)$.

Proof. Write $E:=V \otimes M_{0}$. It is well known that via Serre duality, $\bar{\mu}$ is dual to the cup product map

$$
\bigcup: H^{1}\left(C, \mathcal{O}_{C}\right) \rightarrow \operatorname{Hom}\left(H^{0}(C, E), H^{1}(C, E)\right)
$$

By hypothesis, therefore, $\bigcup$ is surjective. Since $E$ has Euler characteristic zero, $h^{0}(C, E)=$ $h^{1}(C, E)$. Hence there exists $b \in H^{1}\left(C, \mathcal{O}_{C}\right)$ such that $\cdot \cup b: H^{0}(C, E) \rightarrow H^{1}(C, E)$ is injective. The tangent vector $b$ induces a deformation of $M_{0}$ and hence of $E$, which does not preserve any nonzero section of $E$. Therefore, the locus

$$
\left\{M \in \operatorname{Pic}^{g-1-h}(C): h^{0}(C, V \otimes M) \geqslant 1\right\}
$$

is a proper sublocus of $\mathrm{Pic}^{g-1-h}(C)$, so $\Theta_{V}$ is defined. Now we can apply Casalaina-Martin and Teixidor i Bigas [CT11, Proposition 4.1] to obtain the desired equality mult $M_{0} \Theta_{V}=$ $h^{0}\left(C, V \otimes M_{0}\right)$.

### 2.2 Existence of good singular points

In this section, we study global generatedness and Petri trace injectivity of the bundles $V \otimes M$ for $M \in B_{1, g-1}^{r+1}(V)$ for general $C$ and $V$. The main result of this section is the following theorem.

Theorem 2.5. Suppose $C$ is a Petri general curve of genus $g \geqslant(2 r+2)(2 r+1)$ and $V \in S U_{C}(r)$ a general bundle. Then there exists $M \in \Theta_{V}$ such that $h^{0}(C, V \otimes M)=r+1$, and both $V \otimes M$ and $K_{C} \otimes M^{-1} \otimes V^{*}$ are globally generated and Petri trace injective.

The proof of this theorem has several ingredients. We begin by constructing a stable bundle $E_{0}$ with some of the properties we are interested in. Let $F$ be a semistable bundle of rank $r-1$ and degree $(r-1)(g-1)-1$, and let $N$ be a line bundle of degree $g$.

Lemma 2.6. A general extension $0 \rightarrow F \rightarrow E \rightarrow N \rightarrow 0$ is a stable vector bundle.
Proof. Any subbundle $G$ of $E$ fits into an exact diagram

## GENERIC InJECTIVITY OF THE THETA MAP

where $D$ is an effective divisor on $C$. If $\iota_{2}=0$, then $\mu(G)=\mu\left(G_{1}\right) \leqslant \mu(F)<\mu(E)$. Suppose $\iota_{2} \neq 0$, and write $s:=\operatorname{rk}\left(G_{1}\right)$. If $s \neq 0$, the semistability of $F$ implies that

$$
\operatorname{deg}\left(G_{1}\right) \leqslant s(g-1)-\frac{s}{r-1}
$$

so in fact $\operatorname{deg}\left(G_{1}\right) \leqslant s(g-1)-1$. As $\operatorname{deg}(N)=g$, we have $\operatorname{deg}(G) \leqslant(s+1)(g-1)$. Thus we need only exclude the case where $\operatorname{deg}\left(G_{1}\right)=s(g-1)-1$ and $D=0$, so $\iota_{2}=\operatorname{Id}_{N}$. In this case, the existence of the above diagram is equivalent to $[E]=\left(\iota_{1}\right)_{*}[G]$ for some extension $G$, that is, $[E] \in \operatorname{Im}\left(\left(\iota_{1}\right)_{*}\right)$.

It therefore suffices to check that

$$
\left(\iota_{1}\right)_{*}: H^{1}\left(C, \operatorname{Hom}\left(N, G_{1}\right)\right) \rightarrow H^{1}(C, \operatorname{Hom}(N, F))
$$

is not surjective. This follows from the fact, easily shown by a Riemann-Roch calculation, that $h^{1}\left(C, \operatorname{Hom}\left(N, F / G_{1}\right)\right)>0$.

If $s=0$, then we need to exclude the lifting of $G=N(-p)$ for all $p \in C$, that is,

$$
[E] \notin \bigcup_{p \in C}\left(\operatorname{Ker}\left(H^{1}(C, \operatorname{Hom}(N, F)) \rightarrow H^{1}(C, \operatorname{Hom}(N(-p), F))\right)\right)
$$

A dimension count shows that this locus is not dense in $H^{1}(C, \operatorname{Hom}(N, F))$.
Lemma 2.7. Suppose $h^{0}(C, N) \geqslant h^{1}(C, F)$. Then for a general extension $0 \rightarrow F \rightarrow E \rightarrow N \rightarrow 0$, the coboundary map is surjective.

Proof. Clearly it suffices to exhibit one extension $E_{0}$ with the required property. We write $n:=h^{1}(C, F)$ for brevity.

Let $0 \rightarrow F \rightarrow \tilde{F} \rightarrow \tau \rightarrow 0$ be an elementary transformation with $\operatorname{deg}(\tau)=n$ and such that the image of $\Gamma(C, \tau)$ generates $H^{1}(C, F)$. We may assume that $\tau$ is supported along $n$ general points $p_{1}, \ldots, p_{n}$ of $C$ which are not base points of $|N|$. Then $\tau_{p_{i}}$ is generated by an element

$$
\phi_{i} \in\left(\frac{F\left(p_{i}\right)}{F}\right)_{p_{i}}
$$

defined up to nonzero scalar multiple. We write $\left[\phi_{i}\right]$ for the class in $H^{1}(C, F)$ defined by $\phi_{i}$.
Now $h^{0}(C, N) \geqslant n$ and the image of $C$ is nondegenerate in $|N|^{*}$. As the $p_{i}$ can be assumed to be general, they impose independent conditions on sections of $N$. We choose sections $s_{1}, \ldots$, $s_{n} \in H^{0}(C, N)$ such that $s_{i}\left(p_{i}\right) \neq 0$ but $s_{i}\left(p_{j}\right)=0$ for $j \neq i$. For $1 \leqslant i \leqslant n$, let $\eta_{i}$ be a local section of $N^{-1}$ such that $\eta_{i}\left(s_{i}\left(p_{i}\right)\right)=1$.

Let $0 \rightarrow F \rightarrow E_{0} \rightarrow N \rightarrow 0$ be the extension with class [ $E_{0}$ ] defined by the image of

$$
\left(\eta_{1} \otimes \phi_{1}, \ldots, \eta_{n} \otimes \phi_{n}\right)
$$

by the coboundary map $\Gamma\left(C, N^{-1} \otimes \tau\right) \rightarrow H^{1}\left(C, N^{-1} \otimes F\right)$. Then $s_{i} \cup\left[E_{0}\right]=\left[\phi_{i}\right]$ for $1 \leqslant i \leqslant n$. Hence the image of $\cdot \cup\left[E_{0}\right]$ spans $H^{1}(C, F)$.

We now make further assumptions on $F$ and $N$. If $r=2$, then $g \geqslant(2 r+2)(2 r+1)=30$. Hence by the Brill-Noether theory of line bundles on $C$, we may choose a line bundle $F$ of degree $g-2$ with $h^{0}(C, F)=2$ and $|F|$ base point free. If $r \geqslant 3$ : since $g \geqslant 3$, we have $(r-1)(g-1)-1 \geqslant r$. Therefore, by [BBN15, Theorem 5.1] we may choose a semistable bundle $F$ of rank $r-1$ and degree $(r-1)(g-1)-1$ which is globally generated and satisfies $h^{0}(C, F)=r$, so $h^{1}(C, F)=r+1$.

Furthermore, again by Brill-Noether theory, since $g \geqslant(2 r+2)(2 r+1)$ we may choose $N \in \operatorname{Pic}^{g}(C)$ such that $h^{0}(C, N)=2 r+2$ and $|N|$ is base point free. By Lemma 2.7, we may choose an $(r+1)$-dimensional subspace $\Pi \subset H^{0}(C, E)$ lifting from $H^{0}(C, N)$.

## G. H. Hitching and M. Hoff

Proposition 2.8. Let $F, N$ and $\Pi$ be as above, and let $0 \rightarrow F \rightarrow E \rightarrow N \rightarrow 0$ be a general extension. Then the restricted Petri trace map $\Pi \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow H^{0}\left(C, K_{C}\right)$ is injective.

Proof. Choose a basis $\sigma_{1}, \ldots, \sigma_{r+1}$ for $\Pi$. For each $i$, write $\widetilde{\sigma}_{i}$ for the image of $\sigma_{i}$ in $H^{0}(C, N)$.
By Lemma 2.7, there is an isomorphism $H^{1}(C, E) \xrightarrow{\sim} H^{1}(C, N)$. Hence, by Serre duality, the injection $K_{C} \otimes N^{-1} \hookrightarrow K_{C} \otimes E^{*}$ induces an isomorphism on global sections. Choose a basis $\tau_{1}, \ldots, \tau_{2 r+1}$ for $H^{0}\left(C, K_{C} \otimes E^{*}\right)$. For each $j$, write $\widetilde{\tau_{j}}$ for the preimage of $\tau_{j}$ by the aforementioned isomorphism.

For each $i$ and $j$ we have a commutative diagram

where the top row defines the twisted endomorphism

$$
\mu\left(\sigma_{i} \otimes \tau_{j}\right) \in H^{0}\left(C, K_{C} \otimes \operatorname{End} E^{*}\right)=H^{0}\left(C, K_{C} \otimes \operatorname{End} E\right) .
$$

Clearly this has rank one. As it factorises via $K_{C} \otimes N^{-1}$, at a general point of $C$ the eigenspace corresponding to the single nonzero eigenvalue is identified with the fibre of $N^{-1}$ in $E^{*}$. Hence the Petri trace $\bar{\mu}\left(\sigma_{i} \otimes \tau_{j}\right)$ may be identified with the restriction to $N^{-1}$. By the diagram, we may identify this restriction with

$$
\mu_{N}\left(\widetilde{\sigma}_{i} \otimes \widetilde{\tau}_{j}\right) \in H^{0}\left(C, K_{C}\right)
$$

where $\mu_{N}$ is the Petri map of the line bundle $N$. Since $C$ is Petri, $\mu_{N}$ is injective. Hence the elements $\bar{\mu}\left(\sigma_{i} \otimes \tau_{j}\right)=\mu_{N}\left(\widetilde{\sigma_{i}} \otimes \widetilde{\tau_{j}}\right)$ are independent in $H^{0}\left(C, K_{C}\right)$. This proves the statement.

Before proceeding, we need to recall some background on coherent systems (see [BBN08, § 2] for an overview and [BGMN03] for more detail). We recall that a coherent system of type ( $r, d, k$ ) is a pair $(W, \Pi)$ where $W$ is a vector bundle of rank $r$ and degree $d$ over $C$, and $\Pi \subseteq H^{0}(C, W)$ is a subspace of dimension $k$. There is a stability condition for coherent systems depending on a real parameter $\alpha$, and a moduli space $G(\alpha ; r, d, k)$ for equivalence classes of $\alpha$-semistable coherent systems of type $(r, d, k)$. If $k \geqslant r$, then by [BGMN03, Proposition 4.6] there exists $\alpha_{L} \in \mathbb{R}$ such that $G(\alpha ; r, d, k)$ is independent of $\alpha$ for $\alpha>\alpha_{L}$. This 'terminal' moduli space is denoted $G_{L}$. Moreover, the locus

$$
U(r, d, k):=\left\{(W, \Pi) \in G_{L}: W \text { is a stable vector bundle }\right\}
$$

is an open subset of $G_{L}$. For us, $d=r(g-1)$ and $k=r+1$. To ease notation, we write $U:=U(r, r(g-1), r+1)$.

Now let $N_{1}$ be a line bundle of degree $g$ with $h^{0}\left(C, N_{1}\right) \geqslant r+2$. Let $F$ be as above, and let $0 \rightarrow F \rightarrow E \rightarrow N_{1} \rightarrow 0$ be a general extension.

Lemma 2.9. For a general subspace $\Pi \subset H^{0}(C, E)$ of dimension $r+1$, the coherent system $(E, \Pi)$ defines an element of $U$.

Proof. Recall the bundle $E_{0}$ defined in Lemma 2.7, which clearly is generically generated. Let us describe the subsheaf $E_{0}^{\prime}$ generated by $H^{0}\left(C, E_{0}\right)$.

## GENERIC InJECTIVITY OF THE THETA MAP

Write $p_{1}+\cdots+p_{r+1}=: D$. Clearly $s \cup\left[E_{0}\right]=0$ for any $s \in H^{0}\left(C, N_{1}(-D)\right)$. Since the $p_{i}$ are general points,

$$
h^{0}\left(C, N_{1}(-D)\right)=h^{0}\left(C, N_{1}\right)-(r+1)=\operatorname{dim}\left(\operatorname{Ker}\left(\cdot \cup\left[E_{0}\right]: H^{0}\left(C, N_{1}\right) \rightarrow H^{1}(C, F)\right)\right) .
$$

Therefore, the image of $H^{0}\left(C, E_{0}\right)$ in $H^{0}\left(C, N_{1}\right)$ is exactly $H^{0}\left(C, N_{1}(-D)\right)$. As the subbundle $F \subset E_{0}$ is globally generated, $E_{0}^{\prime}$ is an extension $0 \rightarrow F \rightarrow E_{0}^{\prime} \rightarrow N_{1}(-D) \rightarrow 0$. Dualising and taking global sections, we obtain

$$
0 \rightarrow H^{0}\left(C, N_{1}^{-1}(D)\right) \rightarrow H^{0}\left(C,\left(E_{0}^{\prime}\right)^{*}\right) \rightarrow H^{0}\left(C, F^{*}\right) \rightarrow \cdots
$$

Since both $N_{1}^{-1}(D)$ and $F^{*}$ are semistable of negative degree, $h^{0}\left(C, N_{1}^{-1}(-D)\right)=h^{0}\left(C, F^{*}\right)=0$, so $h^{0}\left(C,\left(E_{0}^{\prime}\right)^{*}\right)=0$.

Now let $\Pi_{1} \subset H^{0}\left(C, E_{0}\right)$ be any subspace of dimension $r+1$ generically generating $E_{0}$. Since $h^{0}\left(C,\left(E_{0}^{\prime}\right)^{*}\right)=0$, by [BBN08, Theorem 3.1(3)] the coherent system $\left(E_{0}, \Pi_{1}\right)$ defines a point of $G_{L}$. Since generic generatedness and vanishing of $h^{0}\left(C,\left(E^{\prime}\right)^{*}\right)$ are open conditions on families of bundles with a fixed number of sections, the same is true for a generic $(E, \Pi)$ where $E$ is an extension $0 \rightarrow F \rightarrow E \rightarrow N_{1} \rightarrow 0$. By Lemma 2.6, in fact ( $E, \Pi$ ) belongs to $U$.

Lemma 2.10. For generic $E$ represented in $U$, we have $h^{0}(C, E)=h^{0}\left(C, K_{C} \otimes E^{*}\right)=r+1$.
Proof. Since $C$ is Petri general, $B_{1, g}^{r+2}$ is irreducible in $\operatorname{Pic}^{g}(C)$. Thus there exists an irreducible family parametrising extensions of the form $0 \rightarrow F \rightarrow E \rightarrow N_{1} \rightarrow 0$ where $F$ is as above and $N_{1}$ ranges over $B_{1, g}^{r+2}$. This contains the extension $E_{0}$ constructed above. By Lemma 2.7, a general element $E_{1}$ of the family satisfies $h^{0}\left(C, E_{1}\right)=r+1$. By semicontinuity, the same is true for general $E$ represented in $U$.

Now by [BBN08, Theorem 3.1(4) and Remark 6.2], the locus $U$ is irreducible. Write $B$ for the component of $B_{r, r(g-1)}^{r+1}$ containing the image of $U$, and $B^{\prime}$ for the sublocus $\{E \in B$ : $\left.h^{0}(C, E)=r+1\right\}$. Set $U^{\prime}:=U \times_{B} B^{\prime}$; clearly $U^{\prime} \cong B^{\prime}$.

Let $\tilde{B} \rightarrow B$ be an étale cover such that there is a Poincaré bundle $\mathcal{E} \rightarrow \tilde{B} \times C$. In a natural way we obtain a commutative cube

where all faces are fibre product diagrams. By a standard construction, we can find a complex of bundles $\alpha: K^{0} \rightarrow K^{1}$ over $\tilde{B}$ such that $\operatorname{Ker}\left(\alpha_{b}\right) \cong H^{0}\left(C, K_{C} \otimes \mathcal{E}_{b}^{*}\right)$ for each $b \in \tilde{B}$. Following [ACGH85, ch. IV], we consider the Grassmann bundle $\operatorname{Gr}\left(r+1, K^{0}\right)$ over $\tilde{B}$ and the sublocus

$$
\mathcal{G}:=\left\{\Lambda \in \operatorname{Gr}\left(r+1, K^{0}\right):\left.\alpha\right|_{\Lambda}=0\right\} .
$$

Write $\mathcal{G}_{1}:=\mathcal{G} \times_{\tilde{B}} \tilde{U}$. The fibre of $\mathcal{G}_{1}$ over $\left(\mathcal{E}_{b}, \Pi\right) \in \tilde{U}$ is then $\operatorname{Gr}\left(r+1, H^{0}\left(C, K_{C} \otimes \mathcal{E}_{b}^{*}\right)\right)$.

## G. H. Hitching and M. Hoff

Now let $E_{0}$ be a bundle as constructed in Lemma 2.7 with $h^{0}\left(C, E_{0}\right)=2 r+2$, and let $\Pi_{0}$ be a generic choice of $(r+1)$-dimensional subspace of $H^{0}\left(C, E_{0}\right)$. We may assume $\tilde{U}$ is irreducible since $U$ is. Since $\tilde{U} \rightarrow U$ is étale, by Lemma 2.8 in fact $U$ is also smooth at $\left(E_{0}, \Pi_{0}\right)$ (cf. [BGMN03, Proposition 3.10]). Therefore, we may choose a one-parameter family $\left\{\left(E_{t}, \Pi_{t}\right): t \in T\right\}$ in $\tilde{U}$ such that $\left(E_{t_{0}}, \Pi_{t_{0}}\right)=\left(E_{0}, \Pi_{0}\right)$ while $\left(E_{t}, \Pi_{t}\right)$ belongs to $\tilde{U}^{\prime}$ for generic $t \in T$. Since the bundles have Euler characteristic zero, for generic $t \in T$ there is exactly one choice of $\left.\Lambda \in \mathcal{G}_{1}\right|_{\left(E_{t}, \Pi_{t}\right)}$. Thus we obtain a section $T \backslash\{0\} \rightarrow \mathcal{G}_{1}$. As $\operatorname{dim} T=1$, this section can be extended uniquely to 0 . We thus obtain a triple $\left(E_{0}, \Pi_{0}, \Lambda_{0}\right)$ where $\Lambda \subset H^{0}\left(C, K_{C} \otimes E_{0}^{*}\right)$ has dimension $r+1$. By Lemma 2.8, this triple is Petri trace injective. Hence

$$
\left(E_{t}, \Pi_{t}, \Lambda_{t}\right)=\left(E, H^{0}(C, E), H^{0}\left(C, K_{C} \otimes E^{*}\right)\right)
$$

is Petri trace injective for generic $t \in T$. Thus a general bundle $E$ represented in $\tilde{U}^{\prime}$ is Petri trace injective.

Furthermore, by [BBN08, Theorem 3.1(4)], a general $(E, \Pi) \in U$ is globally generated (not just generically). Thus we obtain the following proposition.
Proposition 2.11. A general element $E$ of the irreducible component $B \subseteq B_{r, r(g-1)}^{r+1}$ is Petri trace injective and globally generated with $h^{0}(C, E)=r+1$.

We can now prove the theorem.
Proof of Theorem 2.5. Consider the map $a: S U_{C}(r) \times \operatorname{Pic}^{g-1}(C) \rightarrow U_{C}(r, r(g-1))$ given by $(V, M) \mapsto V \otimes M$. This is an étale cover of degree $r^{2 g}$. We write $\bar{B}$ for the inverse image $a^{-1}(B)$. Since $a$ is étale, we have $T_{(V, M)} \bar{B} \cong T_{V \otimes M} B$ for each $(V, M) \in B$. In particular,

$$
\begin{equation*}
\operatorname{dim} \bar{B}=\operatorname{dim} B=\operatorname{dim} U_{C}(r, r(g-1))-(r+1)^{2} . \tag{6}
\end{equation*}
$$

We write $p$ for the projection $S U_{C}(r) \times \operatorname{Pic}^{g-1}(C) \rightarrow S U_{C}(r)$, and $p_{1}$ for the restriction $\left.p\right|_{\bar{B}}: \bar{B} \rightarrow S U_{C}(r)$.
Claim. $p_{1}$ is dominant.
To see this: for $(V, M) \in \bar{B}$, the locus $p_{1}^{-1}(V)$ is identified with an open subset of the twisted Brill-Noether locus

$$
B_{1, g-1}^{r+1}(V)=\left\{M \in \operatorname{Pic}^{g-1}(C): h^{0}(C, V \otimes M) \geqslant r+1\right\} \subseteq \operatorname{Pic}^{g-1}(C) .
$$

Moreover, for each such $(V, M)$, we have

$$
\operatorname{dim}_{M}\left(p_{1}^{-1}(V)\right)=\operatorname{dim}\left(T_{M}\left(B_{1, g-1}^{r+1}(V)\right)\right)=\operatorname{dim} \operatorname{Im}(\bar{\mu})^{\perp}
$$

Since $V \otimes M$ is Petri trace injective, this dimension is $g-(r+1)^{2}$. By semicontinuity, a general fibre of $p_{1}$ has dimension at most $g-(r+1)^{2}$. Therefore, in view of (6), the image of $p_{1}$ has dimension at least

$$
\left(\operatorname{dim} U_{C}(r, r(g-1))-(r+1)^{2}\right)-\left(g-(r+1)^{2}\right)=\operatorname{dim} U_{C}(r, r(g-1))-g=\operatorname{dim} S U_{C}(r)
$$

As $S U_{C}(r)$ is irreducible, the claim follows.
We can now conclude the proof. Let $V \in S U_{C}(r)$ be general. By the claim, we can find $(V, M) \in \tilde{P}$ such that $h^{0}(C, V \otimes M)=r+1$ and $V \otimes M$ is globally generated and Petri trace injective. By Proposition 2.4, the theta divisor $\Theta_{V}$ exists and satisfies mult ${ }_{M} \Theta_{V}=$ $h^{0}(C, V \otimes M)=r+1$. Finally, by considering a suitable sum of line bundles, we see that the involution $E \mapsto K_{C} \otimes E^{*}$ preserves the component $\bar{B}$. Since a general element of $\bar{B}$ is globally generated, in general both $V \otimes M$ and $K_{C} \otimes M^{-1} \otimes V^{*}$ are globally generated.

## Generic injectivity of the theta map

## 3. Reconstruction of bundles from tangent cones to theta divisors

### 3.1 Tangent cones

Let $Y$ be a normal variety and $Z \subset Y$ a divisor. Let $p$ be a smooth point of $Y$ which is a point of multiplicity $n \geqslant 1$ of $Z$. A local equation $f$ for $Z$ near $p$ has the form $f_{n}+f_{n+1}+\cdots$, where the $f_{i}$ are homogeneous polynomials of degree $i$ in local coordinates centred at $p$. The projectivised tangent cone $\mathcal{T}_{p}(Z)$ to $Z$ at $p$ is the hypersurface in $\mathbb{P} T_{p} Y$ defined by the first nonzero component $f_{n}$ of $f$. (For a more intrinsic description, see [ACGH85, ch. II.1].)

Now let $C$ be a curve of genus $g \geqslant(r+1)^{2}$. Let $E$ be a Petri trace injective bundle of rank $r$ and degree $r\left(g-1\right.$ ), with $h^{0}(C, E)=r+1$. By Proposition 2.4 (with $h=g-1$ ), the theta divisor $\Theta_{E}$ is defined and contains the origin $\mathcal{O}_{C}$ of $\operatorname{Pic}^{0}(C)$ with multiplicity $h^{0}(C, E)=r+1$.

By [CT11, Theorem 3.4 and Remark 3.8] (see also Kempf [Kem73]), the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ to $\Theta_{E}$ at $\mathcal{O}_{C}$ is given by the determinant of an $(r+1) \times(r+1)$ matrix $\Lambda=\left(l_{i j}\right)$ of linear forms $l_{i j}$ on $H^{1}\left(C, \mathcal{O}_{C}\right)$, which is related to the multiplication map $\bar{\mu}$ as follows: in appropriate bases $\left(s_{i}\right)$ and $\left(t_{j}\right)$ of $H^{0}(C, E)$ and $H^{0}\left(C, K_{C} \otimes E^{*}\right)$ respectively, $\Lambda$ is given by

$$
\left(l_{i j}\right)=\left(\bar{\mu}\left(s_{i} \otimes t_{j}\right)\right) .
$$

Hence, via Serre duality, $\Lambda$ coincides with the cup product map

$$
\bigcup: H^{0}(C, E) \otimes H^{1}\left(C, \mathcal{O}_{C}\right) \rightarrow H^{1}(C, E)
$$

Thus the matrix $\Lambda=\left(l_{i j}\right)$ is a matrix of linear forms on the canonical space $\left|K_{C}\right|^{*}$.
In the following two subsections, we will show on the one hand that one can recover the bundle $E$ from the determinantal representation of the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ given by the matrix $\Lambda$. On the other hand, up to changing bases in $H^{0}(C, E)$ and $H^{1}(C, E)$ there are only two determinantal representations of the tangent cone, namely $\Lambda$ and $\Lambda^{t}$. Thus the tangent cone determines $E$ up to an involution.

We will denote by $\mathbb{P}=\left|K_{C}\right|^{*}$ the canonical space and by $\varphi$ the canonical embedding $C \hookrightarrow \mathbb{P}$.

### 3.2 Reconstruction of the bundle from the tangent cone

As above, let $\Lambda=\left(l_{i j}\right)$ be the determinantal representation of the tangent cone given by the cup product mapping. We identify the source of $\Lambda$ with $H^{0}(C, E)$ and the target with $H^{1}(C, E)$ :

$$
H^{0}(C, E) \otimes \mathcal{O}_{\mathbb{P}}(-1) \xrightarrow{\Lambda} H^{1}(C, E) \otimes \mathcal{O}_{\mathbb{P}}
$$

We recall that the Serre duality isomorphism sends $b \in H^{1}(C, E)$ to the linear form

$$
\cdot \cup b: H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow H^{1}\left(C, K_{C}\right)=\mathbb{C} .
$$

In the following proofs, we will use principal parts in order to represent cohomology classes of certain bundles. We refer to [Kem83] or [Pau03, § 3.2] for the necessary background. See also Kempf and Schreyer [KS88].

Lemma 3.1. Suppose that $h^{0}(C, E)=r+1$ and $E$ and $K_{C} \otimes E^{*}$ are globally generated. Then the rank of $\left.\Lambda\right|_{C}=\varphi^{*} \Lambda$ is equal to $r=$ rk $E$ at all points of $C$. In particular, the canonical curve is contained in $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$.

## G. H. Hitching and M. Hoff

Proof. For each $p \in C$, write $\beta_{p}$ for a principal part with a simple pole supported at $p$. Then (see [KS88]) the cohomology class $\left[\beta_{p}\right]$ is identified with the image of $p$ by $\varphi$. Therefore, at $p \in C$, the pullback $\left.\Lambda\right|_{C}$ is identified with the cup product map

$$
\left[\beta_{p}\right] \otimes s \mapsto\left[\beta_{p}\right] \cup s .
$$

The kernel of $\left[\beta_{p}\right] \cup$ contains the subspace $H^{0}(C, E(-p))$, which is one-dimensional since $E$ is globally generated and $h^{0}(C, E)=r+1$. If $\operatorname{Ker}\left(\left[\beta_{p}\right] \cup \cdot\right)$ has dimension greater than 1 , then there is a section $s^{\prime} \in H^{0}(C, E)$ not vanishing at $p$ such that

$$
\left[\beta_{p} \cdot s^{\prime}\right]=\left[\beta_{p}\right] \cup s^{\prime}=0 \in H^{1}(C, E) .
$$

By Serre duality, this means that

$$
\left[\beta_{p} \cdot\left\langle s^{\prime}(p), t(p)\right\rangle\right]
$$

is zero in $H^{1}\left(C, K_{C}\right)$ for all $t \in H^{0}\left(C, K_{C} \otimes E^{*}\right)$. Hence the values at $p$ of all global sections of $K_{C} \otimes E^{*}$ belong to the hyperplane in $\left.\left(K_{C} \otimes E^{*}\right)\right|_{p}$ defined by contraction with the nonzero vector $\left.s^{\prime}(p) \in E\right|_{p}$. Thus $K_{C} \otimes E^{*}$ is not globally generated, contrary to our hypothesis.

Remark 3.2. Casalaina-Martin and Teixidor i Bigas in [CT11, §6] prove more generally that if $E$ is a general vector bundle with $h^{0}(C, E)>k r$, then the $k$ th secant variety of the canonical image $\varphi(C)$ of $C$ is contained in $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$.

Proposition 3.3. Let $E$ be a vector bundle with $h^{0}(C, E)=r+1$, such that both $E$ and $K_{C} \otimes E^{*}$ are globally generated. Then the image of $\left.\Lambda\right|_{C}$ is isomorphic to $T_{C} \otimes E$.

Proof. As $\varphi^{*} \mathcal{O}_{\mathbb{P}^{g-1}}(-1) \cong T_{C}$, the pullback $\varphi^{*} \Lambda=\left.\Lambda\right|_{C}$ is a map

$$
\left.\Lambda\right|_{C}: T_{C} \otimes H^{0}(C, E) \rightarrow \mathcal{O}_{C} \otimes H^{1}(C, E)
$$

Write $L:=\operatorname{det}(E)$, a line bundle of degree $r(g-1)$. Then $\operatorname{det}\left(K_{C} \otimes E^{*}\right)=K_{C}^{r} \otimes L^{-1}$. As $K_{C} \otimes E^{*}$ is globally generated, the evaluation sequence

$$
0 \rightarrow K_{C}^{-r} \otimes L \rightarrow \mathcal{O}_{C} \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow K_{C} \otimes E^{*} \rightarrow 0
$$

is exact. For each $p \in C$, the image of $\left.\left(K_{C}^{-r} \otimes L\right)\right|_{p}$ in $H^{0}\left(C, K_{C} \otimes E^{*}\right)$ is exactly $\mathbb{C} \cdot t_{p}$, where $t_{p}$ is the unique section, up to scalar, of $K_{C} \otimes E^{*}$ vanishing at $p$.

Dualising, we obtain a diagram

Here $e_{p}$ can be identified up to scalar with the map $f \mapsto f\left(t_{p}\right)$ where $t_{p}$ is as above.
Now for each $p \in C$, the image

$$
\left[\beta_{p}\right] \cup H^{0}(C, E) \subset H^{1}(C, E) \cong H^{0}\left(C, K_{C} \otimes E^{*}\right)^{*}
$$

annihilates $t_{p} \in H^{0}\left(C, K_{C} \otimes E^{*}\right)$, since the principal part $\beta_{p} \cdot t_{p}$ is everywhere regular. Therefore, $\Lambda_{C}$ factorises via $\operatorname{Ker}(e)=T_{C} \otimes E$. Since $\operatorname{rk}\left(\left.\Lambda\right|_{C}\right) \equiv r$ by Lemma 3.1, we have $\operatorname{Im}\left(\left.\Lambda\right|_{C}\right) \cong$ $T_{C} \otimes E$.

## Generic injectivity of the theta map

Remark 3.4. A straightforward computation shows also that

$$
\operatorname{Ker}\left(\left.\Lambda\right|_{C}\right) \cong T_{C} \otimes L^{-1} \quad \text { and } \quad \operatorname{Coker}\left(\left.\Lambda\right|_{C}\right) \cong K_{C}^{r} \otimes L^{-1}
$$

We will also want to study the transpose $\Lambda^{t}$, which we will consider as a map

$$
\Lambda^{t}: \mathcal{O}_{\mathbb{P}}(-1) \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow \mathcal{O}_{\mathbb{P}} \otimes H^{1}\left(C, K_{C} \otimes E^{*}\right)
$$

The proof of Proposition 3.3 also shows the following corollary.
Corollary 3.5. Let $E$ and $\Lambda$ be as above. Then the image of $\left.\Lambda^{t}\right|_{C}$ is isomorphic to $E^{*}$.
Remark 3.6. In order to describe the cokernel of $\left.\Lambda\right|_{C}$, it is also enough to know at which points of $C$ a row of $\left.\Lambda\right|_{C}$ vanishes. Dualising the sequence

$$
0 \rightarrow K_{C}^{r} \otimes L^{-1} \rightarrow \mathcal{O}_{C} \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right) \rightarrow K_{C} \otimes E^{*} \rightarrow 0
$$

we see that $H^{0}\left(C, K_{C} \otimes E^{*}\right)^{*}$ is canonically identified with a subspace of $H^{0}\left(C, K_{C}^{r} \otimes L^{-1}\right)$. Using the description of

$$
T_{C} \otimes H^{0}(C, E) \xrightarrow{\Lambda_{C}} \mathcal{O}_{C} \otimes H^{1}(C, E) \xrightarrow{\sim} \mathcal{O}_{C} \otimes H^{0}\left(C, K_{C} \otimes E^{*}\right)^{*}
$$

as in the above proof, we see that a row vanishes exactly in a divisor associated to $K_{C}^{r} \otimes L^{-1}$. Hence, the cokernel is isomorphic to $K_{C}^{r} \otimes L^{-1}$.

### 3.3 Uniqueness of the linear determinantal representation of the tangent cone

In order to show the desired uniqueness of the determinantal representation of the tangent cone, we use a classical result of Frobenius. See [Fro97] and also for a modern proof [Die49, Wat87] and the references therein. For the sake of completeness we will give a sketch of a proof following Frobenius.

Proposition 3.7. Suppose $r \geqslant 1$. Let $A$ and $B$ be $(r+1) \times(r+1)$ matrices of independent linear forms, such that the entries of $A$ are linear combinations of the entries of $B$ and $\operatorname{det}(A)=c \cdot \operatorname{det}(B)$ for a nonzero constant $k \in \mathbb{C}$. Then, there exist invertible matrices $S, T \in \mathrm{Gl}(r+1, \mathbb{C})$, unique up to scalar, such that $A=S \cdot B \cdot T$ or $A=S \cdot B^{t} \cdot T$.

Proof by Frobenius [Fro97, pp. 1011-1013]. Note that for $r \geqslant 1$ only one of the above cases can occur and the matrices $S$ and $T$ are unique up to scalar. Indeed, let $A=S B T=S^{\prime} B T^{\prime}$ and set $b_{i i}=1$ and $b_{i j}=0$ if $i \neq j$; then $S T=S^{\prime} T^{\prime}$. Set $U=T\left(T^{\prime-1}\right)=S\left(S^{\prime-1}\right)$; thus $U B=B U$. Since $U$ commutes with every matrix, we have $U=k \cdot E_{r}$ and hence $S^{\prime}=k \cdot S$ and $T^{\prime}=1 / k \cdot T$. Similarly, one can show that $B^{t}$ is not equivalent to $B$. Note also that there is no relation between any minors of $A$ or $B$.

For $l=0, \ldots, r$, let $c_{i j}^{l}$ be the coefficient of $b_{l l}$ in $a_{i j}$ and let $y$ be a new variable. We substitute $b_{l l}$ with $b_{l l}+y$ in $A$ and $B$ and get new matrices, denoted by $\left(a_{i j}+y \cdot c_{i j}^{l}\right)$ and $B^{l}$, respectively. Since $\operatorname{det} B^{l}$ is linear in $y$, the coefficient of $y^{2}$ in $\operatorname{det}\left(a_{i j}+y \cdot c_{i j}^{l}\right)=\operatorname{det} B^{l}$ has to vanish. But the coefficient is the sum of products of $2 \times 2$ minors of $\left(c_{i j}^{l}\right)$ and $(r-1) \times(r-1)$ minors of $A$. Since there are no relations between any minors of $A$, all $2 \times 2$ minors of ( $c_{i j}^{l}$ ) vanish. Hence, $\left(c_{i j}^{l}\right)$ has rank one for any $l$ and we can write $c_{i j}^{l}=p_{i}^{l} q_{j}^{l}$ where $p^{l}$ and $q^{l}$ are column and row vectors, respectively.

## G. H. Hitching and M. Hoff

Let $B_{0}=\left.B\right|_{\left\{b_{i j}=0, i \neq j\right\}}$ and $A_{0}=\left.A\right|_{\left\{b_{i j}=0, i \neq j\right\}}$. Then

$$
A_{0}=P B_{0} Q,
$$

where $P=\left(p_{i}^{l}\right)_{0 \leqslant i, l \leqslant r}$ and $Q=\left(q_{j}^{l}\right)_{0 \leqslant l, j \leqslant r}$. Since $\operatorname{det}\left(A_{0}\right)=c \cdot \operatorname{det}\left(B_{0}\right)=c \cdot b_{00} \cdot \ldots \cdot b_{r r}$, we get $\operatorname{det}(P) \cdot \operatorname{det}(Q)=c$, hence $P$ and $Q$ are invertible.

Let $\widetilde{B}=P^{-1} A Q^{-1}$. By definition $\left.\widetilde{B}\right|_{\left\{b_{i j}=0, i \neq j\right\}}=B_{0}$. Thus, the entries $\widetilde{b_{i j}}$ for $i \neq j$ and $v_{i}=\widetilde{b_{i i}}-b_{i i}$ are linear functions in $b_{i j}$ for $i \neq j$. Furthermore, we have

$$
\operatorname{det}(\widetilde{B})=\operatorname{det}\left(P^{-1} A Q^{-1}\right)=\operatorname{det}\left(P^{-1} Q^{-1}\right) \cdot \operatorname{det}(A)=\frac{1}{c} \cdot c \cdot \operatorname{det}(B)=\operatorname{det}(B)
$$

Comparing the coefficients of $b_{11} b_{22} \cdots b_{r r}$ in $\operatorname{det}(\widetilde{B})$ and $\operatorname{det}(B)$, we get $v_{0}=0$. Similarly, $v_{i}=0$ for $0 \leqslant i \leqslant r$. Comparing the coefficients of $b_{22} \cdots b_{r r}$, we get $b_{12} b_{21}=\widetilde{b_{12}} \widetilde{b_{21}}$ and in general

$$
b_{i j} b_{j i}=\widetilde{b_{i j} b_{j i}}, \quad i \neq j
$$

Comparing the coefficients of $b_{33} \cdots b_{r r}$, we get $b_{12} b_{23} b_{31}+b_{21} b_{13} b_{32}=\widetilde{b_{12}} \widetilde{b_{23}} \widetilde{b_{31}}+\widetilde{b_{21}} \widetilde{b_{13} b_{32}}$ and in general

$$
b_{i j} b_{j k} b_{k i}+b_{j i} b_{i k} b_{k j}=\widetilde{b_{i j} b_{j k} \sigma_{k i}}+\widetilde{b_{j i} b_{i k} \sigma b_{k j}}, \quad i \neq j \neq k \neq i
$$

A careful study of these equations shows that either

$$
\widetilde{b_{i j}}=\frac{k_{i}}{k_{j}} b_{i j} \quad \text { and } \quad \widetilde{B}=K B K^{-1} \quad \text { or } \quad \widetilde{b_{i j}}=\frac{k_{i}}{k_{j}} b_{j i} \quad \text { and } \quad \widetilde{B}=K B^{t} K^{-1}
$$

where $K=\left(k_{i} \delta_{i j}\right)_{0 \leqslant i, j \leqslant r}$. The claim follows.
We now assume that $E$ is a Petri trace injective bundle. Let $\Lambda=\left(l_{i j}\right)$ be a determinantal representation of the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ as above. By Petri trace injectivity, the matrix $\Lambda$ is $(r+1)$-generic (see [Eis88] for a definition), that is, there are no relations between the entries $l_{i j}$ or any subminors of $\Lambda$.

Corollary 3.8. For a curve of genus $g \geqslant(r+1)^{2}$ and a Petri trace injective bundle $E$ with $r+1$ global sections of degree $r(g-1)$, any determinantal representation of the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right) \subset\left|K_{C}\right|^{*}$ is equivalent to $\Lambda$ or $\Lambda^{t}$.

Proof. Let $\alpha$ be any determinantal representation of the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ in $\left|K_{C}\right|^{*}$. Then, $\alpha$ is an $(r+1) \times(r+1)$ matrix of linear entries, since the degree of the tangent cone is $r+1$. Furthermore, the entries $\alpha_{i j}$ of $\alpha$ are linear combinations of the entries $l_{i j}$ of $\Lambda$. Indeed, assume for some $k, l$ that $\alpha_{k l}$ is not a linear combination of the $l_{i j}$. Then $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ would be the cone over $V\left(\alpha_{k l}\right) \cap \mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$. Hence, the vertex of $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$ defined by the entries $l_{i j}$ would have codimension strictly less than $(r+1)^{2}$, a contradiction to the independence of the $l_{i j}$. The corollary follows from Proposition 3.7.

## 4. Injectivity of the theta map

Theorem 4.1. Suppose $r \geqslant 2$. Let $C$ be a Petri general curve of genus $g \geqslant(2 r+2)(2 r+1)$. Then the theta map $\mathcal{D}: S U_{C}(r) \rightarrow|r \Theta|$ is generically injective.

## GENERIC InJECTIVITY OF THE THETA MAP

Proof. Let $V \in S U_{C}(r)$ be a general stable bundle. By Theorem 2.5, there exists $M \in \Theta_{V}$ such that $h^{0}(C, V \otimes M)=r+1$, the bundle $V \otimes M=: E$ is Petri trace injective, and $E$ and $K_{C} \otimes E^{*}$ are globally generated.

Note that tensoring by $M^{-1}$ defines an isomorphism $\Theta_{V} \xrightarrow{\sim} \Theta_{E}$ inducing an isomorphism $\mathcal{T}_{M}\left(\Theta_{V}\right) \xrightarrow{\sim} \mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$. In order to use the results of the previous sections, we will work with $\Theta_{E}$. Now let

$$
\alpha: \mathcal{O}_{\mathbb{P}^{g-1}}(-1) \otimes \mathbb{C}^{r+1} \rightarrow \mathcal{O}_{\mathbb{P}^{g-1}} \otimes \mathbb{C}^{r+1}
$$

be a map of bundles of rank $r+1$ over $\mathbb{P}^{g-1}$ whose determinant defines the tangent cone $\mathcal{T}_{\mathcal{O}_{C}}\left(\Theta_{E}\right)$. By Corollary 3.8 , the map $\alpha$ is equivalent either to $\Lambda$ or $\Lambda^{t}$, where $\Lambda$ is the representation given by the cup product mapping as defined in $\S 3$. Therefore, by Proposition 3.3 and Corollary 3.5, the image $E^{\prime}$ of $\left.\alpha\right|_{C}$ is isomorphic either to $T_{C} \otimes E=V \otimes M \otimes T_{C}$ or to $E^{*}=V^{*} \otimes M^{-1}$. Thus $V$ is isomorphic either to

$$
\begin{equation*}
E^{\prime} \otimes K_{C} \otimes M^{-1} \quad \text { or to } \quad\left(E^{\prime}\right)^{*} \otimes M^{-1} \tag{7}
\end{equation*}
$$

Now since in particular $g>(r+1)^{2}$, the open subset $\left\{M \in \operatorname{Pic}^{g-1}(C): h^{0}(C, V \otimes M)=r+1\right\} \subseteq$ $B_{1, g-1}^{r+1}(V)$ has a component of dimension $g-(r+1)^{2} \geqslant 1$. Therefore, we may assume that $M^{2 r} \not \not K_{C}^{r}$. Thus only one of the bundles in (7) can have trivial determinant. Hence there is only one possibility for $V$.

In summary, the data of the tangent cone $\mathcal{T}_{M}\left(\Theta_{V}\right)$ and the point $M$, together with the property $\operatorname{det}(V)=\mathcal{O}_{C}$, determine the bundle $V$ up to isomorphism. In particular, $\Theta_{V}$ determines $V$.

Remark 4.2. The involution $M \mapsto K_{C} \otimes M^{-1}$ defines an isomorphism of varieties $\Theta_{V} \xrightarrow{\sim} \Theta_{V^{*}}$. We observe that the transposed map $\Lambda^{t}$ occurs naturally as the cup product map defining the tangent cone $\mathcal{T}_{K_{C} \otimes M^{-1}}\left(\Theta_{V^{*}}\right)$.

Remark 4.3. If $C$ is hyperelliptic, then the canonical map factorises via the hyperelliptic involution $\iota$. Thus the construction in Proposition 3.3 can never give bundles over $C$ which are not $\iota$-invariant. We note that Beauville [Bea88] showed that in rank two, if $C$ is hyperelliptic then the bundles $V$ and $\iota^{*} V$ have the same theta divisor.

## Acknowledgements

The authors would like to thank Ciro Ciliberto, Peter Newstead, Christian Pauly, Frank-Olaf Schreyer and Edoardo Sernesi for helpful discussions and comments on this work.
