

Antidepressants should be prescribed in line with NICE guidance. There are 3 relevant documents from NICE and the Trust has developed local guidelines for use of antidepressants in the relevant circumstances. An audit into prescribing of all psychotropic medication prescribed by adult mental health services was undertaken. Data includes the full prescribing for 936 patients (300 inpatients and 636 outpatients).

Of the 936 patients 526 patients (56%) were prescribed antidepressants. The prescribing of antidepressants is 95% monotherapy in line with trust and NICE guidance. There is a small amount of combination therapy some of which should be investigated further.

The SSRI antidepressants are recognised first choice antidepressants on the basis of efficacy and cost and 211 (42%) of the trust prescribing was SSRIs. However paroxetine is no longer recommended in the trust for the treatment of depression and there were 33 instances of prescribing paroxetine.

Other antidepressants may be chosen second or third line except for dosulepin which is not recommended for use and phenelzine which is only recommended as third line.

288 (58%) represented other antidepressants with 26 being for dosulepin.

Treatment with antidepressants should be as monotherapy unless the patient has recognised poor response to treatment. The addition of mirtazepine or mianserin to an SSRI is recognised as the most suitable combination therapy. There are 27 instances of prescribing more than one antidepressant, 11 of these show compliance with NICE guidance.

A Randomized and double-blinded clinical trial of Venlafaxine HCL sustained release capsules for treatment in adolescents with major depression

W.D. Ji^{1,2}, H.F. Chang^{1,2}, S.C.H. Yang³, C.H. Yang⁴, X.Q. Huang⁵, J.X. Zhou⁶, T.Y. Guo⁷. ¹Department of Psychiatry, Changning Mental Health Center, Shanghai, China ²The Hospital of Bio-X Center of Shanghai Jiaotong University, Shanghai, China ³Henan Mental Health Center, Xinxiang, China ⁴Wenzhou Medical College, Wenzhou, China ⁵West China University of Medical Science, Chengdu, China ⁶Shenzhen Children's Hospital, Shenzhen, China ⁷Shenzhen University, Shenzhen, China

Background and Aims: To evaluate the efficacy and safety of venlafaxine HCL sustained release capsules in treatment of depression in adolescents.

Methods: A randomized double blind and double dummy clinical trial enrolled 60 adolescents patients with depression, who were randomized 1:1 to administer venlafaxine HCL sustained release capsules 150 mg or fluoxetine 20 mg daily for 8 weeks. The efficacy of both treatment groups was evaluated based on the Hamilton Depression Scale and Clinical General Impression Scale pre- and post-treatment.

Results: The scores of Hamilton Depression Scale at the end of therapy were significantly reduced compared with the baseline in both groups ($P < 0.01$). The efficacy rate of venlafaxine HCL sustained release capsules versus fluoxetine treatment was 70.0% and 65.5%, respectively; the P value showed no statistical difference ($P > 0.05$). The common adverse reactions included dry mouth, insomnia, dizziness, and loss of appetite.

Conclusion: Venlafaxine HCL sustained release capsules is effective and safe agent for adolescents with major depression.

Escitalopram in the treatment of elderly patients with MDD

A. Theodorou, C. Kalkavoura, O. Theodoropoulou, P. Theodoropoulou, E. Tzebelikos. Department of Psychiatry, Sismanoglio General Hospital, Athens, Greece

Objective: To evaluate the efficacy and safety of escitalopram in an open-label, 8 weeks study.

Methods: Twenty seven (27) elderly patients suffering from MDD, according to DSMIV, were included in the study (17 female/10 male, average age 76.3). All patients were treated with escitalopram (dose range 10-20 mg, mean daily dose 16.48 mg). The assessment of antidepressant efficacy was performed using 17-item Hamilton Depression Rating Scale (HAMD17) and Geriatric Depression Scale (GDS). Safety measures included adverse events, vital signs and body weight. All the evaluations were performed at baseline and at week 8.

Results: Twenty five (25) patients concluded the study and two (2) patients discontinued treatment prematurely due to non-compliance. Escitalopram showed significant reduction in both HAMD-17 (-8.2) and GDS total score (-7.2). The percentage at endpoint of HAMD17 response was 44% and remission rates 24%. The most frequent adverse events were nausea in two patients (8%) and headache in four patients (16%). No significant changes were observed regarding vital signs. The mean body weight at baseline was 72.3 and at endpoint 73.1.

Conclusion: Escitalopram was well tolerated and efficacious in reducing symptoms of depression in elderly patients over the 8 week treatment period.

Does a diagnosis of depression or the prescription of an antidepressant influence hypnotic use in primary care?

J. Donoghue², M. Lader¹. ¹King's College, London, UK ²School of Pharmacy & Chemistry, John Moores University, Liverpool, UK

No recommendations or surveys of hypnotic use have taken into account the need to manage disturbed sleep in depression, a key symptom experienced by between 50% and 90% of patients. We investigated the impact of a diagnosis of depression/prescription of an antidepressant on hypnotic treatment in patients newly prescribed an hypnotic in primary care in the UK.

Data relating to new hypnotic prescriptions for 10 years (1996-2005) were obtained from the DIN-Link database. Patients (>15 years) were included if they received a new prescription for an hypnotic medicine and followed up for 1 year.

The proportion of patients newly prescribed an hypnotic who also received a diagnosis of depression increased from 11.1% to 17.4%. For each year of the study, a diagnosis of depression was associated with an increase in the length of treatment with hypnotics: in 2005, the average length of continuous treatment with an hypnotic in depressed patients was 80 days - 30% higher than non-depressed patients. The co-prescription of an antidepressant with hypnotic had similar results in 2005, the proportion of depressed patients prescribed an antidepressant who received an hypnotic for more than 3 months was 31% - over 10 times greater than those not prescribed an antidepressant.

In patients newly prescribed hypnotic medicine, a diagnosis of depression or the prescription of an antidepressant increases the length of hypnotic treatment, suggesting that disturbed sleep is an intractable feature of depressive illness, and that commonly prescribed
