Abstract

The *Onthophagus anthracinus* Harold, 1873 (Coleoptera: Scarabaeidae: Scarabaeinae: Onthophagini) species complex of the *Onthophagus landolti* Harold, 1880 species group is established and analysed. A new species, *O. etlaensis*, is described from this group. *Onthophagus mextexus* Howden and Cartwright, 1970 is considered a valid species and *O. knulli* Howden and Cartwright, 1963 is placed in synonymy with *O. durangoensis* Balthasar, 1939 new synonymy. A key for the *O. anthracinus* species complex is presented along with photographs and illustrations of the main taxonomic differences. An update of the *O. landolti* species group is presented.

Introduction

Onthophagus Latreille, 1802 (Coleoptera: Scarabaeidae: Scarabaeinae: Onthophagini) is a hyperdiverse genus, comprising about 2200 described species (Rossini *et al.* 2018a, 2018b); it is part of the largest clade of Scarabaeinae dung beetles, the Onthophagini, with over 2500 species (Scholtz *et al.* 2009; Philips 2011). This genus is widely distributed, exhibiting its highest diversity in the Afrotropical and Oriental regions. Scholtz *et al.* (2009) consider that part of their evolutionary success resides in having a generally small size, their use of many food sources, as well as having relatively short life cycles and simple nests plus a rapid generation turnover with multiple breeding episodes.

The genus *Onthophagus* has also emerged as a promising model for undertaking studies in evolutionary developmental biology and ecological development. Specifically, the genus offers promising research avenues for integrating developmental genetics underpinning phenotypic diversity, especially through the analysis of horn expression and other secondary sexual traits (Moczek 2011). *Onthophagus* have also become an insect model for studying the evolution of parental care (Hunt and House 2011).

The genus *Onthophagus* has been the focus of detailed taxonomic group analyses for the Western Hemisphere. Among the recent general studies, we can cite an analysis of the *O. hircus* Billberg, 1815 species group and its *O. oscullatii* Guérin-Méneville, 1855 species complex

(Rossini *et al.* 2018a, 2018b), as well as an analysis of the *O. fuscus* Boucomont, 1932 species complex (Joaqui *et al.* 2019).

The *O. landolti* Harold, 1880 species group was established by Zunino and Halffter (1997) and redefined by Zunino (2003). Recently, Howden and Génier (2004) and Moctezuma *et al.* (2016) studied this group. Howden and Génier (2004) revised the *O. lecontei* Harold, 1871–*O. subopacus* Robinson, 1940 species complex, whereas, Moctezuma *et al.* (2016) established another species complex for *O. mariozuninoi* Delgado *et al.*, 1993.

In this paper, we establish the *O. anthracinus* Harold, 1873 species complex, with description of *O. etlaensis* new species from Oaxaca, Mexico. In addition, *Onthophagus mextexus* Howden and Cartwright, 1970 is resurrected from previous synonymy and *O. knulli* Howden and Cartwright, 1963 is considered to be a junior synonym of *O. durangoensis* Balthasar, 1939.

Materials and methods

Specimens were studied from the collections of the Canadian Museum of Nature (CMNC) in Ottawa, Ontario, Canada; the Instituto de Ecología, Xalapa (IEXA), Xalapa, Mexico; the Universidad del Valle de Guatemala, Guatemala City, Guatemala; and the Museo Nacional, Santo Domingo de Heredia, Costa Rica. The holotype, allotype, and 177 paratypes of *O. etlaensis* are deposited in the Colección Entomológica (Entomology Collection), Instituto de Ecología, Xalapa, Mexico. Further paratypes are deposited in the following institutes: six paratypes in the Seção de Entomologia da Coleção Zoológica da Universidade Federal de Mato Grosso, Cuiabá, Brazil (CEMT); 17 paratypes in the Canadian Museum of Nature, Ottawa, Ontario, Canada; and six paratypes in the personal collection of Julián Blackaller, Tlalpan, Mexico (JB).

Body measurements were made to the nearest 0.1 mm using an ocular micrometer with a Zeiss Stemi DV4 stereoscope, Jena, Germany. Genital dissections and preparations were done following the techniques described by Zunino (1978). Genital structures were stored in microvials with glycerin.

Photographs of *O. anthracinus*, *O. durangoensis*, and *O. etlaensis* were taken by Susana Guzmán-Gómez (Instituto de Biología, Universidad Nacional Autónoma de México, Mexico City, Mexico) using a Zeiss AXIO Zoom V16 microscope, a Zeiss AxioCam MRc5 camera, and the Zeiss efficient navigation multifocal technology programme (Zeiss, Jena, Germany). The photographs of *O. alluvius* Howden and Cartwright, 1963, *O. knulli*, and *O. mextexus* were taken by François Génier (CMNC) using a Leica Z16 system and Leica Application Suite software for image stacking (Leica, Wetzlar, Germany). Photographs of the aedeagi were taken by François Génier (CMNC) and Fernando Escobar-Hernández (IEXA). Serge Laplante (Canadian National Collection of Insects, Arachnids, and Nematodes, Ottawa, Ontario, Canada) took photographs of the holotypes of *O. knulli* and *O. monticolus* Howden and Cartwright, 1963. Jiří Hájek (Národní Muzeum, Prague, Czech Republic) took photographs of the syntypes of *O. durangoensis* Balthasar, 1939. Sara Rivera-Gasperín and Fernando Escobar-Hernández (IEXA) took photographs of the internal sac lamellae of *O. anthracinus* and *O. etlaensis*.

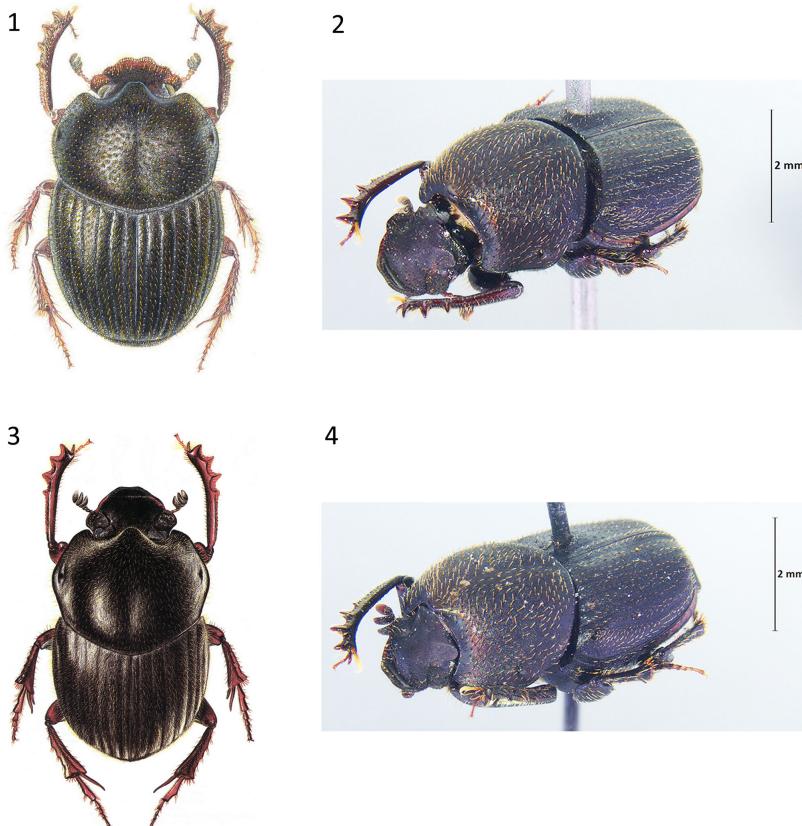

We use the phylogenetic species concept in its diagnosability version according to Zachos (2016: 125), as proposed by Wheeler and Platnick (2000: 58), where a species is defined as “the smallest aggregation of (sexual) populations or (asexual) lineages diagnosable by a unique combination of character states”.

Onthophagus etlaensis Kohlmann, Escobar-Hernández, and Arriaga-Jiménez, new species

(two females) (CMNC); "México, Reserva Comunitaria San Pablo Ebla, Oaxaca. 23-IX-16, coprotrampa. x- -96.723551 W, y- 17.175472°N, bosque de encino, 2325 m. Arriaga A. y Arenas A. Col." (one male, one female) (CMNC); "México, Reserva Comunitaria San Pablo Ebla, Oaxaca. 20-IX-16, coprotrampa. x- -96.732386 W, y- 17.170454°N, bosque de encino, 2151 m. Arriaga A. y Arenas A. Col." (one male, one female) (CMNC).

Type locality. La Mesita, San Pablo Ebla (17°9'50.68"N, 96°44'25.92"W, 1935 m), Oaxaca, Mexico.

Diagnosis. Pygidium almost flat; very shallowly, indistinctly punctate; alutaceous basally; apex slightly to moderately shiny. Large pronotal punctures (75 µm) separated about one diameter with distinct margins, not umbilicate, with a shiny ring and small shallow secondary nonsetate punctures sparsely interspersed. Pronotum crossed longitudinally and in the middle by a sulcus in major males, surrounding pronotal area convex.

Description. Holotype. Major male (Figs. 1–2). Length: 6.1 mm. Humeral width: 3.4 mm. Weakly shiny, opaque black. Clypeal margin sharply reflexed anteriorly, feebly so laterally; anterior edge faintly emarginate. Clypeal disc with few coarse punctures distributed across width. Frons with scattered shallow punctures. Clypeal disc and frons almost flat and lacking both clypeal and frontal carinae, the latter being poorly developed behind the eyes; surface between punctures finely alutaceous. Genal margin noticeably arcuate laterally, anteriorly forming a distinct, obtuse indentation with the clypeal margin; gena sharply and obtusely angulate posteriorly opposite the pronotal angles; genal surface slightly concave and with scattered, shallow punctures. Small eyes, five facets wide and emarginate, separated by about 16 eye widths. Occiput with scattered shallow punctures.

Pronotum (Fig. 13) moderately convex and margined anteriorly and laterally, pronotal protuberance conical broad and evenly arched, weakly projecting over the posterior portion of the head. Pronotal surface distinctly alutaceous and with two sizes of punctures: larger punctures annular with margins sharply defined, centrally with an erect reddish-yellow seta, the large punctures usually separated by approximately one diameter; small secondary punctures half the diameter of large punctures and not as numerous, scattered among large punctures, umbilicate in shape and lacking setae. Elytral striae with feebly shiny and vaguely punctate; intervals opaquely alutaceous with irregular double rows of small shiny tubercles; the base of each tubercle with a fine, reddish-yellow seta. Pygidium slightly longer than broad; opaquely alutaceous, slightly to moderately shiny apex, only slightly convex; covered sparsely with pale yellow setae, interspersed with small shiny punctures. Ventral surfaces, including antennae, black to blackish brown. Metaventrite surface coarsely punctate, more so laterally where the surface between punctures is finely alutaceous; base of metaventrite with large, coarse punctures, each bearing pale yellow setae. Ventrates, except for the first, with a row of setigerous punctures across their basal margin;

last segment narrowed medially. Aedeagus like in Figure 19. Lamella copulatrix like in Figure 22. Prothoracic legs greatly elongate, the apices of the profemora extending slightly beyond the pronotal margin; protibiae long, slender, and recurved, with a pronounced apical conical projection and a long yellow pencil of setae protruding above the apical spine; all femora with scattered, coarse punctures, each puncture bears a pale yellow seta.

Variation. Length: 4.5–6.7 mm. Width: 2.5–3.5 mm. The colour of the lateral side and apical border of the elytra can vary from black to reddish brown.

Male pronotal protuberance can vary from evenly rounded to slightly notched in the middle. Male minors with pronotum less convex, protibiae with apical projection shorter, profemur barely extending to the lateral pronotal margin.

Females differ with clypeus slightly reflexed anteriorly, broadly, somewhat angularly emarginate; clypeal disc coarsely, rugosely punctate, punctures often with brownish-yellow setae; clypeal carina distinct (sometimes absent) but only slightly and rather evenly elevated above clypeal-frontal surface. Frons behind carina with a few distinct coarse punctures; frontal carina low but distinct, generally of uniform height; gena scarcely flared, only very obtusely angulate near pronotal angles and with coarse punctures. Area between female clypeal and frontal carina can vary from slightly to heavily and coarsely punctate. Pronotum less convex, pronotal protuberance indicated by a rounded swelling. Pygidium approximately as broad as long. Prothoracic legs stubby and shorter and the apex of the profemur barely reaches the lateral pronotal margin; protibia proportionately shortened; apical projection and pencil of setae lacking; apical spine as long as the three basal tarsomeres. Last ventrite not emarginate, approximately the same width throughout.

Etymology. Ebla + *ensis*. Ebla being a Nahuatl word, meaning: “Place where beans are abundant”. Also, this is the name of the locality, San Pablo Ebla. The order of authorship for this new species reflects the amount of work contributed to the description.

Distribution and ecology. This species occurs in Oaxaca, Mexico (Fig. 5) at Reserva Comunitaria San Pablo Ebla (Sierra Norte), 1900–3000 m; San José del Pacífico, San Mateo Río Hondo and south of Juchatengo (Sierra Sur), 1800–2500 m; Sierra Mixe at Zempoaltepetl, Santa María Tlahuitoltepec, and Santa María Yacochi, from 2400–2600 m. It has been collected in acahual (abandoned agricultural fields undergoing regeneration), grassland, cloud forest, *Quercus* Linnaeus (Fagaceae) forests, and *Pinus*-*Quercus* forest (*Pinus* Linnaeus, Pinaceae) and seems to be more abundant in *Quercus* forests. Specimens have been collected using dung-baited and carrion-baited pitfall traps, by hand, and in cattle (*Bos taurus* Linnaeus, 1758; Artiodactyla: Bovidae) and horse (*Equus caballus* Linnaeus, 1758; Perissodactyla: Equidae) manure.

Taxonomic placement. *Onthophagus etlaensis* belongs to the *O. anthracinus* species complex, part of the *O. landolti* species group. This species has many similarities to *O. anthracinus*. *Onthophagus etlaensis* has larger pronotal punctures (75 µm), separated by at least one diameter, pronotum traverse along its middle longitudinally by an evident sulcus in major males and the pronotal area around it convex; whereas, *O. anthracinus* has smaller pronotal punctures (50 µm) separated by 1–2 diameters, pronotal midline well marked in major males and the pronotal area around it flattened and forming a rhombus. The pygidium of *O. etlaensis* is opaquely alutaceous and is slightly to moderately shiny, much less so than in *O. alluvius* or *O. durangoensis*.

The aedeagus has been studied for this species complex (Figs. 16–20). All species north of the Isthmus of Tehuantepec, including *O. etlaensis*, have an evident ring near the base of the aedeagus. On the contrary, *O. anthracinus* has a poorly developed and indistinct ring at the phallobase (Fig. 17). There are also fine differences in the structure of the parameres separating *O. etlaensis* from *O. anthracinus*; the first species has a straight frontal margin of the parameres as seen in lateral view, whereas the second species has a curved margin (Figs. 17, 19); the first species has a slender apex of the parameres as seen in the lateral view, whereas the second species has a much broader apex (Fig. 1). The lamella copulatrix of the internal sac (Figs. 21–22) is very

similar in both species. These characteristics hold true for the populations examined from *O. anthracinus* originating from Chiapas (Mexico), Guatemala, and Costa Rica. As Howden and Cartwright (1963) observed, the type of punctures is one of the main characters for separating the different species. The Oaxacan specimens are constant in having large punctures (75 µm), whereas the specimens studied from Chiapas to Costa Rica have consistently smaller (50 µm) punctures.

It seems likely that Bates (1887: 77) in his redescription of *O. anthracinus* included specimens of *O. etlaensis*, as he indicated Oaxaca and Juquila as distribution localities.

Habitat affinities. *Onthophagus etlaensis* occupies similar ecological niches to *O. anthracinus*: *Quercus*, *Pinus*-*Quercus*, and *Pinus* forests in mountainous regions (Fig. 6).

Taxonomic considerations, notes, and new localities

Onthophagus alluvius Howden and Cartwright, 1963

Onthophagus alluvius (Figs. 7–8, 11, 16) is a well-established and much studied species. Elias et al. (1995) found this species in fossil packrat middens in the Bolsón de Mapimí, in the Chihuahuan Desert (Mexico), for a Late Glacial and Holocene paleoenvironmental reconstruction study. It was found to be present in the 3.0–3.5 thousand of years before present chronosequence at Puerto de Ventanillas, Coahuila (Mexico), where this species has not been recorded through present-day collecting. Another interesting mention of *O. alluvius* is by Cave (2005) who cites its presence in dog dung in Austin, Texas, United States of America.

This species was formerly known from Texas in the United States of America and from Nuevo León, Coahuila (see comment above), Tamaulipas, Querétaro, San Luis Potosí, and Hidalgo in Mexico. It is here recorded for the first time for Oaxaca, Mexico: Santiago Chazumba, San Sebastián de la Frontera, 8.vii.1999, GPS-52 (two females); San Juan Bautista Cuicatlán, Santiago Dominguito, 14–16.vii.1999, 1320 m, selva intacta, human dung, A. Díaz (two females); Carretera Oaxaca-Cuicatlán a 50 km de Oaxaca, 14.vii.1999, dead cow, Alfonso Díaz (one female); Yanhuitlán, Oaxaca, 4.vi.1967, G. Halffter, V. Halffter, and P. Reyes (one male). All specimens deposited in the Instituto de Ecología, Xalapa collection.

Onthophagus anthracinus Harold, 1873

Howden and Cartwright (1963: 65) found the name *Onthophagus anthracinus* Harold, 1873 to be preoccupied by *Onthophagus anthracinus* Faldermann, 1835, which had been described from Transcaucasia in the Russian Empire. Kolenati (1846: 12) later established *O. anthracinus* Faldermann, 1835 to be a synonym of *O. histeroides* Ménétriés, 1832 (which was later transferred to the genus *Caccobius* Thomson, 1859). Consequently, the name *Onthophagus anthracinus* Harold, 1873 must be considered as a primary junior homonym of *O. anthracinus* Faldermann, 1835.

The International Commission on Zoological Nomenclature (1999) (Article 23.9.5) states that “When an author discovers that a species-group name in use is a junior primary homonym (Article 53.3) of another species group name also in use, but the names apply to taxa not considered congeneric after 1899, the author must not automatically replace the junior homonym; the case should be referred to the Commission for a ruling under the plenary power and meanwhile prevailing usage of both names is to be maintained [Art. 82].” This Article also indicates that the senior homonym should be in use, which is not the case with Faldermann’s name. *O. anthracinus* Harold, 1873 is a junior primary homonym that is currently in use and has not been considered congeneric with its senior homonym after 1899. So, although Faldermann’s name is not in use, one can interpret the spirit of the Article as to preserve the usage of junior primary homonyms that have been in use, by not being considered congeneric as its senior homonym for a long time.

One can consider that this does not violate the principle that no two taxa should share the same name; therefore, we do here maintain the use of *O. anthracinus* Harold as a valid name. We have submitted a case to the International Commission on Zoological Nomenclature as directed in Article 23.9.5 for the conservation of the specific name *Onthophagus anthracinus* Harold, 1873 and it is presently under review as case number 3807.

Onthophagus anthracinus (Figs. 3–4, 14, 17, 21) is known to occur from Chiapas, Mexico to Chiriquí, Panama. We cite here localities that were studied for the present analysis. Mexico, Chiapas: 5 km W San Cristóbal de las Casas, 8000', 13–16.viii.1969, pine-oak forest, S.J. Peck (one male, eight females); 3 miles NW San Cristóbal de las Casas, 29.v.1969, H.F. Howden (two males, nine females); 6 miles E San Cristóbal de las Casas, 2.vi.1969, H.F. Howden (one male, two females); 10 miles E Teopisca, 11–12.v.1969, H.F. Howden (two males, four females); junction of highways 190 and 195, 8.v.1969, H.F. Howden (one male, two females). All of the Chiapas specimens are from the Canadian Museum of Nature. The following specimens represent country records for Guatemala: Baja Verapaz, San Rafael Chilascó, 1700 m, viii.2000, horse manure, A. Higueros (two males); Baja Verapaz, San Rafael Chilascó, 1700 m, 17.iii.2000, H. Morales (one female); Huehuetenango, road between Bulej and junction of San Mateo Ixatán-Nentón, 2700 m, conifer forest, 22.vii.1988, E.B. Cano (three females); Sacatepequez, Florencia, 15.ix.1990, J Martínez (two males, one female); San Marcos, La Fraternidad, 1900 m, viii.1997, cloud forest, J. Monzón (one male); San Marcos, La Fraternidad, 1900 m, ix.1998, A.C. Bailey and J. Monzón (one male, one female); Totonicapán, San Cristóbal Totonicapán, 2300 m, 9.vii.1995, E.B. Cano (one male, one female). All of the Guatemala specimens are from the Universidad del Valle de Guatemala.

***Onthophagus durangoensis* Balthasar, 1939**

In their catalogue of the Onthophagini of the Western Hemisphere, Pulido Herrera and Zunino (2007) placed *O. mextexus* Howden and Cartwright, 1970 in synonymy with *O. durangoensis* Balthasar, 1939. However, *O. mextexus* is reported to be distributed from Texas, United States of America to Puebla, Mexico, and therefore does not match the toponymy given by Balthasar (1939) of Durango. Moreover, the description of *O. durangoensis* is clear that it has an apically shiny and punctate pygidium with the rest of the surface alutaceous and nearly impunctate (Balthasar 1939: 45–46). These are one of the main characteristics given by Howden and Cartwright (1963) to differentiate *O. knulli* Howden and Cartwright, 1963 from *O. mextexus*. It would seem, therefore, that Pulido Herrera and Zunino (2007) confused *O. knulli* with *O. mextexus*, establishing an incorrect synonymy.

The two specimens (male and female) Balthasar (1939) used for his original description carry labels reporting the type locality as Canelas, Durango (Bezděk and Hájek 2013). Balthasar (1939) also made the comment that his new species probably pertained to group 8, as established by Boucomont (1932).

A photographic comparison of the types of *O. durangoensis* (Figs. 12, 15, 18) (taken by Jiří Hájek), with *O. knulli* and *O. monticolus* (taken by Serge Laplante), confirms without doubt that *O. mextexus* is a valid species and not a synonym of *O. durangoensis*, as erroneously established by Pulido Herrera and Zunino (2007). It also revealed that *O. durangoensis* and *O. knulli* are conspecific, based on the pronotal puncture pattern seen in the photographic analysis. Therefore, we correct this error and establish the following new synonymy: *O. knulli* Howden and Cartwright, 1963 = *O. durangoensis* Balthasar, 1939.

This species has been reported for Arizona and New Mexico in the United States of America and Durango, Jalisco, Colima, Michoacán, Morelos, Federal District, and Oaxaca in Mexico. It is here reported for the first time for Sinaloa, Mexico based on three female specimens from Copala, 7.vii.1968, Halffter, Martínez, Reyes (Instituto de Ecología, Xalapa collection). The presence of *O. durangoensis* in Oaxaca merits confirmation, because intensive collecting by A.A.-J. in this state

over the last years has not produced any specimens of this taxon. Martínez-Falcón *et al.* (2018) report it (as *O. knulli*) for the *Juniperus* Linnaeus (Cupressaceae) forests of the state of Hidalgo, Mexico. This is probably an identification error; *O. mextexus* and *O. alluvius* have been reported for this state (Delgado and Márquez 2006).

***Onthophagus mextexus* Howden and Cartwright, 1970**

As previously mentioned, Pulido Herrera and Zunino (2007) erroneously established the following synonymy: *O. mextexus* Howden and Cartwright, 1970 (replacement name for *O. monticolus* Howden and Cartwright 1963) = *O. durangoensis* Balthasar. *Onthophagus mextexus* is here resurrected as a valid species.

This species has received recent attention (Huerta Crespo and Cruz Rosales 2016; Huerta Crespo *et al.* 2016; Halffter *et al.* 2018) as an important component for sustainable tropical cattle ranching in the State of Veracruz, Mexico. It is found in cloud, *Quercus*, *Pinus*-*Quercus* forests, secondary vegetation, shaded plantations, and paddocks. It can be found in moderately technified ranches that are surrounded by forests.

The species is known to occur in Texas in the United States of America and Nuevo León, Hidalgo, Puebla, Guanajuato, and Veracruz in Mexico. It is here reported for the first time for San Luis Potosí based on one male and seven female specimens from 20 km W Xilitla, 1600 m, 12.vi–6.viii.1983, cloud forest, flight interception trap, S. and J. Peck (Canadian Museum of Nature collection).

The *Onthophagus anthracinus* species complex

We establish the *O. anthracinus* species complex as having the following characteristics: anterior edge of pronotal punctures lacking tubercles; pygidial punctures very shallow, at least in basal half, sometimes deep and distinct if apical half of pygidium is shiny; male with pronotal protuberance; female with protuberance usually feebly indicated; pronotal punctures not crowded, separated by at least one diameter, anterior edge of pronotal punctures lacking any small shiny tubercle; surface dull, alutaceous, brown or black; length less than 7.5 mm.

Key to the species in the *Onthophagus anthracinus* species complex

1. Pygidium apically convex, shiny, and smooth; distinctly punctate; alutaceous basally (Fig. 7). Pronotal punctures with indistinct margin, (Fig. 8) 2
- Pygidium almost flat, shallowly and indistinctly punctate, alutaceous basally; apex less shiny and alutaceous (Fig. 9). Pronotal punctures with distinct margins, often appearing like a shiny, ocellate ring, (Fig. 10) 3
2. Posterior half of metaventrite medially impunctate or with one or two coarse punctures (Fig. 11). Usually occurs in lowland alluvial habitats from Texas, United States of America to Oaxaca, Mexico *Onthophagus alluvius* Howden and Cartwright, 1963
- Posterior half of metaventrite medially with a few coarse punctures near midline, as coarsely punctate medially as laterally with larger punctures (Fig. 12). Usually occurs in montane habitats from Arizona, United States of America to Sierra Madre Occidental and the Transverse Volcanic System (Federal District, Mexico) *Onthophagus durangoensis* Balthasar, 1939

3. Pronotal punctures umbilicate (Fig. 10); small, shallow, nonsetate secondary punctures abundantly scattered among large punctures. Big Bend region of Texas, United States of America to Veracruz, Mexico
..... *Onthophagus mextexus* Howden and Cartwright, 1970
- Pronotal punctures not umbilicate, like a shiny ring (Fig. 13); small, shallow nonsetate secondary punctures sparsely scattered among large punctures. Oaxaca Highlands, Mexico to Chiriquí, Panama 4
4. Pronotal punctures 75 µm in diameter with an evident shiny ring, punctures separated by approximately one puncture diameter (Fig. 13). Pronotal longitudinal sulcus evident in major males (Fig. 13), area around it convex. Phallobase with a distinct ring (Fig. 19), internal sac lamella as in Figure 22. Oaxaca, Mexico
..... *Onthophagus etlaensis* new species
- Pronotal punctures 50 µm in diameter with no evident shiny ring, separated by 1–2 puncture diameters (Fig. 14). Pronotal midline well marked in major males (Fig. 14), pronotal area around it flattened forming a rhombus. Phallobase with an indistinct ring (Fig. 17), internal sac lamella as in Fig. 21. Chiapas, Mexico to Chiriquí, Panama
..... *Onthophagus anthracinus* Harold, 1873
-

The *Onthophagus landolti* species group

Boucomont (1932) published a synopsis of the Neotropical *Onthophagus*. In this work, he established what he called the “8th group” of *Onthophagus*, encompassing the species of what is now called the *O. landolti* species group: *O. anthracinus* Harold, 1873, *O. arizonensis* Schaeffer, 1909, *O. atrosericeus* Boucomont, 1932, *O. chryses* Bates, 1887, *O. columbianus* Boucomont, 1932, *O. cribicollis* Horn, 1881, *O. igualensis* Bates, 1887, *O. iodiellus* Bates, 1887, *O. hoepfneri* Harold, 1869, *O. landolti* Harold, 1880, *O. lecontei* Harold, 1871, *O. longimanus* Bates, 1887, and *O. rufescens* Bates, 1887.

Later, Zunino and Halffter (1997) redefined this group and renamed it the *O. landolti* species group and added: *O. aciculatus* Blatchley, 1928, *O. alluvius* Howden and Cartwright, 1963, *O. brachypterus* Zunino and Halffter, 1997, *O. digitifer* Boucomont, 1932, *O. knausi* Brown, 1927, *O. knulli* Howden and Cartwright, 1963, *O. lebasi* Boucomont, 1932, *O. mariozuninoi* Delgado, Navarrte and Blackaller, 1993, *O. mextexus* Howden and Cartwright, 1970, *O. schaefferi* Howden and Cartwright, 1963, *O. subopacus* Robinson, *O. tuberculifrons* Harold, 1871, and *O. zapotecus* Zunino and Halffter, 1988. Subsequently, Howden and Génier (2004) incorporated the following species to the *O. landolti* species group: *O. altivagans* Howden and Génier, 2004, *O. canelasensis* Howden and Génier, 2004, *O. dubitabilis* Howden and Génier, 2004, *O. gibsoni* Howden and Génier, 2004, and *O. pedester* Howden and Génier, 2004 and established the *O. lecontei*–*O. subopacus* species complex.

Recently, Moctezuma *et al.* (2016) described another species for the *O. landolti* species group, *O. martinpierai* Moctezuma, Rossini, Zunino, Halffter, 2016. They also established another species complex consisting of *O. martinpierai*, *O. mariozuninoi*, and *O. dubitabilis*.

We present below an updated list of the species belonging to the *O. landolti* species group, including three species complexes, the *O. lecontei*–*O. subopacus* species complex as defined by Howden and Génier (2004), the *O. mariozuninoi* species complex as defined by Moctezuma *et al.* (2016), and the *O. anthracinus* species complex as defined in this paper. *Onthophagus columbianus* Boucomont, 1932 drops from this list because it was recently placed in junior synonymy with *Onthophagus elegans* Klug, 1832, a Madagascan species (Rossini and Vaz-de-Mello 2016).

Checklist of the *Onthophagus landolti* species group

Onthophagus anthracinus species complex

Onthophagus alluvius Howden and Cartwright, 1963

Onthophagus anthracinus Harold, 1873

Onthophagus durangoensis Balthasar, 1939

Onthophagus etlaensis Kohlmann, Escobar-Hernández, and Arriaga-Jiménez, new species

Onthophagus mextexus Howden and Cartwright, 1970

Onthophagus lecontei-*Onthophagus subopacus* species complex

Onthophagus altivagans Howden and Génier, 2004

Onthophagus canelasensis Howden and Génier, 2004

Onthophagus gibsoni Howden and Génier, 2004

Onthophagus lecontei Harold, 1871

Onthophagus subopacus Robinson, 1940

Onthophagus mariozuninoi species complex

Onthophagus dubitabilis Howden and Génier, 2004

Onthophagus mariozuninoi Delgado, Navarrete, and Blackaller, 1993

Onthophagus martinpierai Moctezuma, Rossini, Zunino, and Halffter, 2016

Species not assigned to species complexes

Onthophagus aciculatus Blatchley, 1928

Onthophagus atrosericeus Boucomont, 1932

Onthophagus brachypterus Zunino and Halffter, 1997

Onthophagus chrysces Bates, 1887

Onthophagus cribicollis Horn, 1881

Onthophagus digitifer Boucomont, 1932

Onthophagus hoepfneri Harold, 1869

Onthophagus igualensis Bates, 1887

Onthophagus iodiellus Bates, 1887

Onthophagus knausi Brown, 1927

Onthophagus landolti Harold, 1880

Onthophagus lebasi Boucomont, 1932

Onthophagus longimanus Bates, 1887

Onthophagus pedester Howden and Génier, 2004

Onthophagus rufescens Bates, 1887

Onthophagus schaefferi Howden and Cartwright, 1963

Onthophagus tuberculifrons Harold, 1871

Onthophagus zapotecus Zunino and Halffter, 1988

Acknowledgements. We thank Jack Schuster and Enio Cano for allowing B.K. to study the insect collection of the Universidad del Valle de Guatemala and to Dr. Santiago Zaragoza for access to the National Insect Collection of Mexico. We also thank Susana Guzmán-Gómez for taking several photographs used in this paper. We are also indebted to François Génier, from the Canadian Museum of Nature, for the loan of material of the *O. anthracinus* species complex; photographs of *O. alluvius*, *O. knulli*, and *O. mextexus*; and relevant literature and information regarding *O. anthracinus*. We would also like to thank Michele Rossini and François Génier with their help in the interpretation of the International Code of Zoological Nomenclature. We would like to thank Serge Laplante, Canadian National Collection of Insects, Arachnids, and Nematodes, for taking photographs of the holotypes of *O. knulli* and *O. monticolus*; Fernando Vaz-de-Mello for sharing photographs taken by Jiří Hájek from

the Národní Muzeum, Prague, Czech Republic, of the syntypes of *O. durangoensis*; and Sara Rivera-Gasperín from the Institute of Ecology, for taking the photographs of the internal sac lamellae. Last but not least, we would like to thank Jane Segleau for checking the English language. Collections in Oaxaca for the new species were financed by the Rufford Foundation through the RSG grant 20054-1 given to A.A.-J.
