Dietary guidelines^(1,2) for the prevention of cardiovascular disease have not been systematically evaluated in a randomized controlled trial. We carried out a parallel designed randomized controlled trial comparing a cardioprotective diet with a traditional British dietary pattern in healthy non-smoking men and women aged 40–70 years. The cardioprotective diet included salt <6 g/day, saturated fatty acids <10% of food energy, oily fish intake 1–2 portions/week and fruit and vegetables 5 portions/day, and supplied at least half of the cereal intake from wholegrains. The control diet was a typical well-balanced British diet containing less than one serving per month of oily fish. Following a screening visit, potential participants were asked to make 2 × 24 hour urine collections, 2 × 24 hour ambulatory blood pressure (BP) measurements and complete a 4-day dietary record. Participants attended a clinic to have specialised measurements of vascular function made and to provide fasting blood samples, and were then randomly allocated to the diets. Dietary advice, given by a dietitian, was followed up at regular intervals and a variety of foods were provided to aid compliance to the diet. Further 24 hour BP monitoring and urine collections were made at 4–6 weeks, 8 weeks and 12 weeks and further dietary assessments, vascular measurements and blood collections were made at the end of the study. The specified primary outcomes reported here were a 4 mm Hg change in daytime systolic BP and a 5% change in the ratio of total cholesterol:HDL cholesterol (TC:HDL-C). Data were analysed on an intention to treat basis by analysis of covariance adjusting for the baseline value, age, gender, body mass index and ethnicity using STATA version 11.1 (StataCorp, College Station Texas). The CRESSIDA trial (ISRCTN92382106) randomised 165 participants to either the cardioprotective (CP) or a control (C) diet for 12 weeks. Data for the primary outcomes were available for analysis in 162 subjects.

	Daytime systolic BP mm Hg				TC:HDL-C			
	CP (n 80)		C (n 82)		CP (n 80)		C (n 82)	
	Mean	SD	Mean	SD	Mean	SD	Mean	SD
Baseline	124.7	13.1	127.4	12.1	3.46	0.91	3.63	0.98
Follow-up	122.3**	13.5	128.7	13.1	3.31*	0.87	3.59	0.96

* $P < 0.05$, ** $P = 0.001$ compared to control group.

Day-time systolic BP fell by 4.2 mm Hg (95% CI 1.7, 6.7) and the TC:HDL-C by 4.2% (95% CI 0.2, 8.2). These changes are estimated to reduce the risk of fatal heart attack and stroke by 17% and 20% and incident cardiovascular disease by about a third. The dietary intervention was well accepted by the participants and provides evidence to support current dietary guidelines for the prevention of CHD.
