The normalized scores  $s_1^*, s_2^*, \dots, s_n^*$  are exchangeable random variables for the fixed  $n$ , i.e.,  $n$ -exchangeable or finite exchangeable. Their distribution depends on  $n$ , and their correlation is a function of  $n$ . Therefore, if they are a segment of the infinite sequence  $s_1^*, s_2^*, \dots$ , then they are not exchangeable, i.e., not infinite exchangeable and also not stationary. Accordingly, Berman’s theorem [2] (Theorem 2.1 in the article) and Theorems 4.5.2. and 5.3.4. from [5], which hold for stationary sequences, cannot be used in the proofs of Results 2.1. and 2.2. However, from Theorem 1 presented and proved below, for  $P(X_{ij} = 1/2) = p \in [1/3, 1)$  or  $p = 0$ , Results 2.1. and 2.2. follows, and therefore, so do the follow-up Corollaries 2.1. and 2.2.

Let  $I_j^{(n)} = I(s_j^* > x_n(t))$ , where we choose  $x_n(t) = a_n t + b_n$ , in which  $a_n$  and  $b_n$  are as defined in equation (1) in the article:

$$a_n = (2 \log n)^{-1/2}, \quad b_n = (2 \log n)^{1/2} - \frac{1}{2}(2 \log n)^{-1/2}(\log \log n + \log 4\pi).$$

Set  $S_n = I_1^{(n)} + I_2^{(n)} + \dots + I_n^{(n)}$ .

We prove the following result.

**Theorem 1.** For  $p = 0$  or  $p \in [1/3, 1)$  and a fixed value of  $k$ ,  $\lim_{n \rightarrow \infty} P(S_n = k) = e^{-\lambda(t)}(\lambda(t)^k / k!)$ ,  $\lambda(t) = e^{-t}$ .

For  $p = 0$  or  $p \in [1/3, 1)$ , Results 2.1. and 2.2. follow from Theorem 1, since  $P(s_{(n-j)}^* \leq x_n) = P(S_n \leq j)$ , and therefore

$$\lim_{n \rightarrow \infty} P(s_{(n-j)}^* \leq x_n) = \lim_{n \rightarrow \infty} P(S_n \leq j) = e^{-e^{-t}} \sum_{k=0}^j \frac{e^{-tk}}{k!}.$$

**Remark 1.** It remains an open problem if Theorem 1 holds also for  $p \in (0, 1/3)$ .

*Proof.* (Theorem 1) The result follows from Assertions presented below. Set

$$\pi_i^{(n)} = P(I_i^{(n)} = 1), \quad W_n = \sum_{i=1}^n I_i^{(n)}, \quad \lambda_n = E(W_n) = \sum_{i=1}^n \pi_i^{(n)}.$$

**Assertion 1.**

$$d_{TV}(L(W_n), \text{Poi}(\lambda_n)) \leq \frac{1 - e^{-\lambda_n}}{\lambda_n} (\lambda_n - \text{Var}(W_n)) = \frac{1 - e^{-\lambda_n}}{\lambda_n} \left( \sum_{i=1}^n (\pi_i^{(n)})^2 - \sum_{i \neq j} \text{Cov}(I_i^{(n)}, I_j^{(n)}) \right), \quad (\text{A1})$$

where  $d_{TV}(L(W_n), \text{Poi}(\lambda_n))$  is the total variation distance between distributions of  $W_n$  and Poisson distribution with mean  $\lambda_n$ .

**Assertion 2.**

$$\pi_1^{(n)} = P(s_1^* > x_n(t)) \sim 1 - \Phi(x_n(t)), \tag{A2}$$

where  $c_n \sim k_n$  means  $\lim_{n \rightarrow \infty} c_n/k_n = 1$ .

**Assertion 3.**

$$\lim_{n \rightarrow \infty} n\pi_1^{(n)} = \lim_{n \rightarrow \infty} nP(s_1^* > x_n(t)) = \lambda(t) = e^{-t}. \tag{A3}$$

**Assertion 4.**

$$\lim_{n \rightarrow \infty} n^2(P(s_1^* > x_n(t), s_2^* > x_n(t))) = \lambda(t)^2 = e^{-2t}. \tag{A4}$$

In our case, since  $s_1^*, \dots, s_n^*$  are identically distributed,  $\sum_{i=1}^n (\pi_i^{(n)})^2 = nP(s_1^* > x_n)P(s_1^* > x_n)$ , and  $\sum_{i \neq j} \text{Cov}(I_i^{(n)}, I_j^{(n)}) = n(n-1)[P(s_1^* > x_n(t), s_2^* > x_n(t)) - P(s_1^* > x_n(t))P(s_2^* > x_n(t))]$ . Hence, from (A2) and (A3) it follows that

$$\lim_{n \rightarrow \infty} \sum_{i=1}^n (\pi_i^{(n)})^2 = 0. \tag{F1}$$

and from (A3) and (A4) it follows that

$$\lim_{n \rightarrow \infty} \sum_{i \neq j} \text{Cov}(I_i^{(n)}, I_j^{(n)}) = 0. \tag{F2}$$

Then, from (F1) and (F2) it follows that  $\lim_{n \rightarrow \infty} d_{TV}(L(W_n), \text{Poi}(\lambda_n)) = 0$ , and this completes the proof of Theorem 1. □

*Proof. (Assertion 1).* If  $p = P(X_{ij}) = 0$  then  $X_{ij}$  has Bernoulli distribution which is log-concave; or if  $p \geq 1/3$  then  $2X_{ij}$  has log-concave distribution (i.e., for integers  $u \geq 1$ ,  $(p(u))^2 \geq p(u-1)p(u+1)$ ). Proposition 1 and Corollary 2 [6] hold in our model with  $p = 0$  or  $p \in [1/3, 1)$ , and therefore  $\sum_{i=1, i \neq j}^n I_i^{(n)} | I_j^{(n)} = 1$  is stochastically smaller than  $\sum_{i=1, i \neq j}^n I_i^{(n)}$ . Therefore, from the Corollary 2.C.2 [1] we obtain (A1). □

*Proof. (Assertion 2).* Follows from [4, pp. 552–553, Thms. 2 or 3]. □

*Proof. (Assertion 3).* Follows from Assertion 2 combined with [3] result on p. 374 of his book. □

*Proof. (Assertion 4).* Recall that  $s_1 = X_{12} + X_{13} + \dots + X_{1n}$  and  $s_2 = X_{21} + X_{23} + \dots + X_{2n}$ . Hence, condition on the event  $X_{12} = k, k \in \{0, 1/2, 1\}$ ,  $s_1$  and  $s_2$  are independent. Let  $s_{1'} = X_{13} + \dots + X_{1n}, s_{2'} = X_{23} + \dots + X_{2n}$  and denote by  $s_{1'}^*, s_{2'}^*$  the corresponding normalized scores (zero expectation and unit variance). We have,

$$\begin{aligned} P(s_1^* > x_n(t), s_2^* > x_n(t) | X_{12} = k) &= P(s_{1'}^* > x_n(t) | X_{12} = k)P(s_{2'}^* > x_n(t) | X_{12} = k) \\ &= P\left(s_{1'}^* > x_{n-1}(t) \frac{x_n(t)}{x_{n-1}(t)} \sqrt{\frac{n-1}{n-2}} - \frac{\sqrt{2}(k-1/2)}{\sqrt{n-2}}\right) \\ &\quad \times P\left(s_{2'}^* > x_{n-1}(t) \frac{x_n(t)}{x_{n-1}(t)} \sqrt{\frac{n-1}{n-2}} - \frac{\sqrt{2}((1-k)-1/2)}{\sqrt{n-2}}\right) \\ &\sim P(s_{1'}^* > x_{n-1}(t))P(s_{2'}^* > x_{n-1}(t)). \end{aligned} \tag{F3}$$

Combining (F3) with the formula of total probability we obtain

$$P(s_1^* > x_n(t), s_2^* > x_n(t)) \sim P(s_{1'}^* > x_{n-1}(t))P(s_{2'}^* > x_{n-1}(t)),$$

and combining it with Assertion 3 we obtain (A4). □

**Acknowledgement.** I am grateful to Pavel Chigansky for pointing out my mistake.
