

ponent. The percentage of all hospitals reporting at least 1 calendar-month per year of data from the hospitalwide component decreased from 95% in 1986 to 31% in 1995. During this period, use of the hospitalwide component was greater among the hospitals whose first participation in the NNIS system occurred before 1987. Interest by NNIS hospitals in the hospitalwide component decreased from 1987 to 1995. These results suggest an evolution in the way in which NNIS hospitals conduct surveillance of nosocomial infections. The increased interest in surveillance using NNIS components that allow for risk adjustment and interhospital comparison of infection rates suggests that the feasibility and interest for such data are high.

When NNIS began in the 1970s, forms were filled out by hand by infection control personnel and sent to the CDC for analyses and publication of the surveillance data. In 1986, the CDC introduced software for NNIS hospitals, so that data could be entered and sent via floppy disk to the CDC. Beginning in 1991, the CDC distributed the first NNIS Semiannual Report that included comparative data with risk-adjusted nosocomial infection rates. Beginning in 1994, the CDC incorporated these comparative data directly into the software that all NNIS hospitals use. When a hospital calculates its infection rate for an ICU or a surgical procedure, the software automatically compares the hospital's rate with the aggregated NNIS rate, giving the hospital's percentile. In addition, the software performs an appropriate statistical test to help a hospital determine if their rate differs significantly from the pooled mean. As more data are collected at the CDC, aggregated updates are distributed to NNIS hospitals. In June 1996, the CDC implemented telecommunications facilities as a main feature of the NNIS software. This new system allows NNIS hospitals to transmit data to the CDC electronically via telephone lines, rather than by sending floppy disks. In addition, NNIS hospitals may communicate with the CDC via electronic mail, may receive computer assistance interactively, and may obtain software updates automatically.

Since the early 1990s, many US hospitals have attempted to use quantitative standards, or benchmarks, to evaluate the quality of care they provide to patients. Using these benchmarks in infection control has certain limitations, including the need for risk adjustment of infection rates. However, advances in data collection, analysis, dissemination, and technology has allowed the CDC to strengthen its role in aggregating data to evaluate quality of care in hospitals. These advances are helping to keep the CDC's NNIS system the leader in the use of quantitative standards for hospitals to evaluate their quality of care.

Joint Commission Discusses Cooperative Accreditation Agreements

The Joint Commission has begun discussions with five additional accrediting bodies considered as potential candidates for cooperative accreditation agreements. These organizations include the American Association of

Blood Banks, which accredits 2,150 transfusion centers; the Commission on Cancer, which accredits 1,405 hospital-based cancer programs; and the Council on Accreditation of Services for Families and Children, which accredits 675 providers of social, community, and behavioral services. Initial discussions also have begun with two smaller accrediting bodies: the Foundation for Hospice and Homecare, which accredits 90 home care aid programs, and the Medical Quality Commission, which now accredits 30 pre-paid medical groups and is growing.

Needle-Swap Programs Debated

Although currently illegal in most states, needle-exchange programs could prevent more than 11,000 new HIV infections by the end of the decade, two researchers reported at the 11th International Conference on AIDS. Dr. Peter Lurie of the Center for AIDS Prevention Studies at the University of California San Francisco and Ernest Drucker of Albert Einstein College of Medicine in New York said that based on the results of the effectiveness of such programs, as many as 10,000 infections could have been prevented between 1987 and 1995 if clean-needle programs had been implemented. Other researchers praised the study—the first to estimate the national effect of needle exchanges—and said the figures may even underestimate the potential impact of the programs.

Needle exchange programs are controversial, because some people believe that they encourage the use of illegal drugs. Federal funds cannot be used to support the programs, and at least nine states prohibit the distribution of needles without a prescription.

Animal to Human Transplants

In a new report from the Institute of Medicine (IOM), experts cautiously approve animal-to-human transplants, agreeing that the potential benefits of the technology outweigh the risks involved. The panel advises that human clinical trials should proceed only after a sufficient science base has been developed and federal guidelines and other safeguards have been established. The IOM committee issues its recommendations in the report "Xenograft Transplantation: Science, Ethics, and Public Policy," released July 17, 1996.

The transplantation of animal organs and tissue to humans, xenotransplantation, has grown in acceptance in recent years due to a shortage of human donors and a better understanding of the human body's rejection of foreign tissue. However, there has been concern that such transplants also may transfer infectious agents to humans and could endanger public health by introducing new diseases to the human population.

Advocates say xenotransplantation could save thousands of lives each year by providing organs for people who otherwise would die waiting. By the end of 1994, more than 37,000 patients were on the waiting list for donated organs. Approximately 50% of the patients on the waiting list die before a suitable organ becomes available.

Guidelines are being developed by the FDA and the CDC. The IOM committee also recommends that an advisory committee with Health and Human Services be created to coordinate development, oversight, and evaluation of guidelines among federal agencies and other institutions conducting clinical trials. In addition, the IOM committee recommends that guidelines for human clinical trials address four major areas to prevent animal-to-human infection: (1) screening donor animals for infectious organisms and considering the development of specific pathogen-free animals; (2) lifetime surveillance of patients for infectious diseases and periodic surveillance of their families and healthcare workers; (3) establishment of tissue banks for blood and tissue samples from source animals and patients; and (4) establishment of local and national registries of xenotransplant patients, in coordination with international registries.

The committee also considered the possibility of raising animals in a germ-free environment to reduce the risk of infection. The committee concluded that, while the expense to implement the recommendations may be substantial, "the potential of xenotransplantation is great enough to justify funding by federal agencies, private industry, and other sources of research and other programs necessary to minimize the risk of disease transmission."

AMA Guide on AIDS

After years of emphasizing early detection and treatment of HIV infection, the American Medical Association

(AMA) is asking primary care physicians to expand their scope of care with more comprehensive prevention efforts. The AMA, with support from the Henry J. Kaiser Foundation, is sending out a new guide on AIDS education for patients to every US family practitioner, internist, pediatrician, and gynecologist. The guide offers specific directions for helping patients to assess their lifestyle risks and to make choices aimed at infection prevention.

The bulk of the information in the guide focuses on two primary risk factors—sexual behavior and injection drug use. It includes, for example, a section on how to instruct injection drug users to sterilize needles—a discussion that may conflict with some physicians' beliefs about drug use. Dr. James Allen, an AMA public health expert, said the goal is to keep such users from getting AIDS while trying to get them into treatment. The guide also contains a list of risk facts associated with specific sexual practices that the physician can use to objectively discuss HIV prevention and reinforce safer sexual behaviors. There is an illustrated section that provides instruction on how to use a condom.

In addition, the guide emphasizes that healthcare workers must avoid verbal and nonverbal messages that convey philosophical, religious, or moral views about intravenous drug use or sexual behavior.

The AMA said they hope to get the guide out to 200,000 physicians by the end of the year.
