Results: The ANOVA has revealed (p<.05) that for all used sub-tests (Auditory Attention and Response Set, Visual Attention, Statue) the yoga training was superior to the conventional motor training, with effect sizes in the medium-to-high range (0.43-0.88).

Conclusions: The findings from this pilot study suggest that yoga training have positive effect on executive abilities in children with hyperactive-impulsive disorder. It influences predominantly the selective and sustained attention, inhibition, monitoring, and self-regulation. However, it is necessary to do further research into the impact of yoga exercises on the prevention and treatment of hyperactive-impulsive disorder in children.

Introduction: School bullying is a serious problem among tunisian children and adolesent. In our every day practice, we see a considerable number of suicide attempts among bullying victims. Our study tries to provide more information on this phenomenon, in order to organize efficient preventtion measures.

Objectives: Measuring the prevalence of bullying victimization in the town of Sousse-Tunisia Comparing the prevalence found through a validated measurement tool and a closed end question

Methods: It is a cross-sectional study among a sample of 1127 adolescents, aged 12 to 17 years old. The adolescents were divided in two groups the first group, composed of 527 adolescents, answered a closed end (yes/no) question "Have you been a victim of Bullying"; the second group, composed of 600 adolescents, responded to the "adolescent peer relation instrument".

Results: The first group was composed of 48% of boys and 52% of girls with a mean age of 13,24 ± 0,96. The second group was composed of 50% of boys and 50% of girls with a mean age of 13.76 ±1.37. We found a bullying victimization prevalence of 11% for the first group versus 95.1% for the second group. For both groups we didn't find a significant difference in the prevalence of bullying victimization according to sociodemographic factors except the higher family income that was associates to less bullying victimisation for the first group (p=0,04)

Conclusions: The high prevalence of bullying victimization we found using a validated measurement is alarming in terms of the urgency of interventions to prevent bullying in schools.

Introduction: Bullying is a serious problem for school youth. It is prevalent across the elementary and secondary school years and it has serious consequences for both bullies and victims.

Objectives: The aim of this study was to investigate the relationship between self-esteem and bullying behavior.

Methods: We conducted a cross-sectional study including children enrolled in two high schools in Sousse, Tunisia. The students were asked to complete two questionnaires: the Adolescent Peer Relations Instrument witch is a multidimensional scale designed to assess bullying involvement both as target and perpetrator and the Rosenberg self-esteem scale.

Results: We recruited 600 adolescent. The mean age of our population was 13.76 ±1.37 and the sex ratio was 1. More than 95% of adolescent who reported that they had been victims of bullying had a very low self-esteem comparing to those who stated that they had never been bullied (4.4%). Our results have also shown that bullies had a lower self-esteem than children who had not bullied others.

Conclusions: We found that both victims and bullies tend to have low self-esteem. Our findings could help to understand better the role that individual characteristics and personal qualities such as self-esteem play on bullying, and provide the scientific knowledge to develop successful strategies to prevent this phenomenon.
