Abstract

Let \( t : \mathbb{F}_p \rightarrow \mathbb{C} \) be a complex valued function on \( \mathbb{F}_p \). A classical problem in analytic number theory is bounding the maximum

\[
M(t) := \max_{0 \leq H < p} \left| \frac{1}{\sqrt{p}} \sum_{0 \leq n < H} t(n) \right|
\]

of the absolute value of the incomplete sums \((1/\sqrt{p}) \sum_{0 \leq n < H} t(n)\). In this very general context one of the most important results is the Pólya–Vinogradov bound

\[
M(t) \leq \|\hat{t}\|_{\infty} \log 3p,
\]

where \( \hat{t} : \mathbb{F}_p \rightarrow \mathbb{C} \) is the normalized Fourier transform of \( t \). In this paper we provide a lower bound for certain incomplete Kloosterman sums, namely we prove that for any \( \varepsilon > 0 \) there exists a large subset of \( a \in \mathbb{F}_p^\times \) such that for \( \text{kl}_{a,1,p} : x \mapsto e((ax + \overline{X})/p) \) we have

\[
M(\text{kl}_{a,1,p}) \geq \left( \frac{1 - \varepsilon}{\sqrt{2\pi}} + o(1) \right) \log \log p,
\]

as \( p \to \infty \). Finally, we prove a result on the growth of the moments of \( \{M(\text{kl}_{a,1,p})\}_{a \in \mathbb{F}_p^\times} \).

1. Introduction

Let \( p \) be a prime number and \( t : \mathbb{F}_p \rightarrow \mathbb{C} \) be a complex valued function on \( \mathbb{F}_p \). A classical problem in analytic number theory is to bound the incomplete sums

\[
S(t, H) := \frac{1}{\sqrt{p}} \sum_{0 \leq n < H} t(n),
\]

for any \( 0 \leq H < p \). In this very general context, one of the most important results is the following:
THEOREM 1.1 (Pólya–Vinogradov bound, [25, 28]). For any $1 \leq H < p$ one has

$$|S(t, H)| \leq \|\hat{t}\|_\infty \log 3p,$$

where $\hat{t} : \mathbb{F}_p \to \mathbb{C}$ is the normalised Fourier transform of $t$

$$\hat{t}(y) := -\frac{1}{\sqrt{p}} \sum_{0 \leq x < p} t(x)e\left(\frac{yx}{p}\right),$$

e(z) := e^{2\pi iz}, and $\|\hat{t}\|_\infty := \max_{x \in \mathbb{F}_p} |\hat{t}(x)|$.

Pólya and Vinogradov proved this bound only in the case where $t = \chi$ is a multiplicative character over $\mathbb{F}_p^\times$. On the other hand, their methods can be applied to any periodic function over $\mathbb{Z}$ (see [9, p. 2] for a proof of Theorem 1.1). Notice that this bound is non-trivial as soon as $H \geq \|\hat{t}\|_\infty \sqrt{p} \log 3p$. If one defines

$$M(t) := \max_{0 \leq H < p} |S(t, H)|,$$

then the Pólya-Vinogradov bound is equivalent to

$$M(t) \leq \|\hat{t}\|_\infty \log 3p.$$

A natural question that arises in this setting is the following: given a function $t : \mathbb{F}_p \to \mathbb{C}$, is the Pólya-Vinogradov bound sharp for $t$? And if it is not, what is the best possible bound?

1.1. Kloosterman sums, Birch Sums and main results

The aim of this paper is to study the cases of Kloosterman sums and Birch sums. We recall here the definitions of these two objects:

i) Kloosterman sums. For any $a, b \in \mathbb{F}_p^\times$, consider

$$k_{a, b, p} : x \mapsto e\left(\frac{ax + b\overline{x}}{p}\right)$$

where $\overline{x}$ denotes the inverse of $x$ modulo $p$. The complete sum

$$Kl(a, b; p) := \frac{1}{\sqrt{p}} \sum_{1 \leq x < p} e\left(\frac{ax + b\overline{x}}{p}\right)$$

is called the Kloosterman sum associated to $a, b$. The Riemann hypothesis for curves over finite fields implies $|Kl(a, b; p)| \leq 2$ ([29]).

ii) Birch sums. For any $a, b \in \mathbb{F}_p^\times$, consider

$$b_{a, b, p} : x \mapsto e\left(\frac{ax + bx^3}{p}\right).$$

The Birch sum associated to $a, b$ is

$$Bi(a, b; p) := \frac{1}{\sqrt{p}} \sum_{1 \leq x < p} e\left(\frac{ax + bx^3}{p}\right).$$

In this case as well, an application of the Riemann hypothesis for curves over finite fields yields to the bound $|Bi(a, b; p)| \leq 2$ ([29]).
On the size of the maximum of incomplete Kloosterman sums

Kloosterman sums and Birch sums arise in many different areas of analytic number theory such as applications of the circle method, spectral theory, the divisor problem, equidistribution questions, etc..

It is shown in [21, proposition 4·1] that \( M(\text{k}_a, 1, p) \) and \( M(\text{b}_a, 1, p) \) can be arbitrarily large when \( a \) varies over \( \mathbb{F}_p^* \) and \( p \) goes to infinity: in fact,

\[
\lim_{p \to \infty} \max_{a \in \mathbb{F}_p^*} M(\text{k}_a, 1, p) = \lim_{p \to \infty} \max_{a \in \mathbb{F}_p^*} M(\text{b}_a, 1, p) = \infty.
\]

We will prove the following lower bounds:

**THEOREM 1·2.** Let \( 0 < \varepsilon < 1 \). For all \( p \), there exists \( S_{p, \varepsilon} \subset \mathbb{F}_p^* \) such that:

(i) for any \( a \in S_{p, \varepsilon} \) one has

\[
M(\text{k}_a, 1, p) \geq \left( \frac{1 - \varepsilon}{\sqrt{2\pi}} + o(1) \right) \log \log p;
\]

(ii) \( |S_{p, \varepsilon}| \gg \varepsilon p^{\frac{1 - \log 16}{\log p}} \).

The same holds if one replaces \( M(\text{k}_a, 1, p) \) by \( M(\text{b}_a, 1, p) \).

Roughly speaking, the proof of Theorem 1·2 relies on the fact that we can simultaneously control the sign and the size of \( 2(\log p)^{1-\varepsilon} \) Kloosterman (or Birch) sums. Indeed we will prove

**PROPOSITION 1·3.** Let \( 0 < \varepsilon < 1 \). For every prime \( p \) there exists \( S_{p, \varepsilon} \subset \mathbb{F}_p^* \) such that for any \( a \in S_{p, \varepsilon} \) and for every \( 1 \leq n \leq (\log p)^{1-\varepsilon} \)

\[
\text{K}(an, 1; p) \geq \sqrt{2},
\]

and for every \( -(\log p)^{1-\varepsilon} \leq n \leq -1 \)

\[
\text{K}(an, 1; p) \leq -\sqrt{2}.
\]

Moreover \( |S_{p, \varepsilon}| \gg \varepsilon p^{\frac{1 - \log 16}{\log p}} \). The same is true if we replace \( \text{K} \) by \( \text{Bi} \).

Actually, we are going to prove a slightly more general version of Theorem 1·2 (see next section).

1·1·1. The growth of the even moments

In the second part of the paper, we focus our attention on the growth of the even moments of \( \{ M(\text{k}_a, 1, p) \}_{a \in \mathbb{F}_p^*} \) and \( \{ M(\text{b}_a, 1, p) \}_{a \in \mathbb{F}_p^*} \) as \( p \to \infty \), obtaining:

**THEOREM 1·4.** There exist two absolute constant \( 0 < c < 1 < C \) such that as \( p \to \infty \) one has

\[
(c^{2k} + o(1))(\log k)^{2k} \leq \frac{1}{p - 1} \sum_{a \in \mathbb{F}_p^*} M(\text{k}_a, 1, p)^{2k} \leq ((Ck)^{2k} + o(1))(\log \log p)^{2k},
\]

for any fixed \( k \geq 1 \).
THEOREM 1.5. There exist two absolute constant \( 0 < c < 1 < C \) such that as \( p \to \infty \) one has
\[
(c^{2k} + o(1))(\log k)^{2k} \lesssim \frac{1}{p - 1} \sum_{a \in \mathbb{F}_p^*} M(bi_{a,1,p})^{2k} \lesssim (C^{2k} + o(1)) P(k),
\]
for any fixed \( k \geq 1 \), where \( P(k) := \exp(4k \log k + k \log \log k + o(k)) \).

From Theorem 1.5 we get the following

COROLLARY 1.6. There exist two absolute constants \( B, b > 0 \) such that as \( A \to \infty \),
\[
\exp(-\exp(bA)) \leq \liminf_{p \to \infty} \frac{1}{p - 1} |\{a \in \mathbb{F}_p^* : M(bi_{a,1,p}) > A\}| \leq \exp\left(-\exp\left( B A^{1/2-o(1)} \right) \right).
\]

1.2. Remarks and related works

(i) Notice that in Theorem 1.4 and 1.5 the lower bounds for the moments are identical but the upper bounds are substantially different: namely, the upper bound in Theorem 1.4 depends on both \( p \) and \( k \), while the one in Theorem 1.5 is stronger, since it depends only on \( k \). In the proof of Theorem 1.5, we use the estimate
\[
\left| \sum_{N \leq x \leq N+H} e\left(\frac{ax + x^3}{p}\right) \right| \ll H^{1-\varepsilon}
\]
uniformly for any \( 1 < N < p, \quad p^{1/2-\varepsilon/2} < H < p^{1/2+\varepsilon/2} \) and \( a \in \mathbb{F}_p^* \) which is a consequence of the Weyl inequality ([16, lemma 20.3]). The analogous estimate that would be used in Theorem 1.4 (to achieve the same upper bound as in Theorem 1.5) is
\[
\left| \sum_{N \leq x \leq N+H} e\left(\frac{ax + x}{p}\right) \right| \ll H^{1-\varepsilon}
\]
uniformly for any \( 1 < N < p, \quad p^{1/2-\varepsilon/2} < H < p^{1/2+\varepsilon/2} \) and \( a \in \mathbb{F}_p^* \), but it is only conjectured (see for example Hooley’s \( R^2 \)-assumption, [15, p. 44]). We remark that this stronger bound for Theorem 1.4 would imply an analogous of 1.6 (obtained from Theorem 1.5) to Kloosterman sums.

(ii) We remark that Corollary 1.6 essentially recovers [21, theorem 1.6], with a slightly weaker upper bound. On the other hand, the techniques presented in [21] cannot provide any non trivial upper bound on the moments of the maximum of incomplete Kloosterman sums.

(iii) In [1], it is shown that there exists a constant \( C > 0 \) such that for any \( 1 \ll A \leq (2/\pi)(\log \log p - 2 \log \log \log p - C) \) one has that
\[
\frac{1}{p - 1} |\{a \in \mathbb{F}_p^* : M(bi_{a,1,p}) > A\}| = \exp\left(-\exp\left(\frac{\pi A}{2} + O(1) \right) \right).
\]
This is a much more precise result than Corollary 1.6, and it is obtained by a refinement of the argument presented in [22]. On the other hand, the argument in [1], [22] provides only a lower bound in the case of Kloosterman sums, i.e. one can show that there exists
On the size of the maximum of incomplete Kloosterman sums

a constant $D > 0$ such that for any $1 \ll A \leq (2/\pi)(\log \log p - 2 \log \log \log p - D)$
one has

\[
\frac{1}{p - 1} |\{a \in \mathbb{F}_p^\times : M(\text{kl}_{a,1,p}) > A\}| \geq \exp \left(-\exp\left(\frac{\pi A}{2} + O(1)\right)\right). \tag{1.4}
\]

In particular, it seems that the upper bound in Theorem 1.4 is new. We remark that also in [1, 22] the difference between incomplete Birch sums and incomplete Kloosterman sums is due to the fact that the bound in (1.2) is only conjectured. Finally, we notice
that (1.3) and (1.4) imply that there exist $S^1_{\rho}$, $S^2_{\rho} \subset \mathbb{F}_p^\times$ such that $|S^1_{\rho}|, |S^2_{\rho}| \gg p^{1 - \frac{1}{\log \log p}}$
and

\[
M(\text{Im}(\text{kl}_{a_1,1,p})) \gg \left(\frac{2}{\pi} + o(1)\right) \log \log p, \quad M(\text{Im}(\text{bi}_{a_2,1,p})) \gg \left(\frac{2}{\pi} + o(1)\right) \log \log p \tag{1.5}
\]

for any $a_1 \in S^1_{\rho}$ and $a_2 \in S^2_{\rho}$.

(iv) One should compare our result with the case of incomplete character sums. Paley proved that the Pólya–Vinogradov bound is close to be sharp in this case; in [26] it is shown that there exist infinitely many primes $p$ such that

\[
M\left(\left(\frac{\cdot}{p}\right)\right) \gg \log \log p,
\]

where $(\cdot/p)$ is the Legendre symbol modulo $p$. Similar results were achieved for non-trivial characters of any order by Granville and Soundararajan in [14], and by Goldmakher and Lamzouri in [12] and [13]. On the other hand, Montgomery and Vaughan ([23]) have shown that under the Generalised Riemann Hypothesis (GRH).

\[
M(\chi) \ll \log \log p \tag{1.6}
\]

for any $\chi$, which is the best possible bound up to evaluation of the constant.

1.3. Notations and statement of general versions of the main results

In this section we recall some notions regarding $\ell$-adic trace functions. For a general introduction on this subject we refer the reader to [6]. Basic statements and references can also be found in [7] and [11]. In what follows, $p$, $\ell > 2$ are distinct primes and $i : \overline{\mathbb{Q}}_\ell \hookrightarrow \mathbb{C}$ is a fixed isomorphism. Let $\mathcal{F}$ be a middle-extension $\ell$-adic sheaf on $\overline{\mathbb{A}}^1_{\mathbb{F}_p}$ pure of weight 0.

For any $x \in \overline{\mathbb{A}}^1_{\mathbb{F}_p}$ one defines

\[
t_{\mathcal{F},n}(x) := i(\text{Tr}(\text{Fr}_{p^n}(x)|\mathcal{F}_x)),
\]

where $\text{Fr}_{p^n}$ is the geometric Frobenius automorphism of $\mathbb{F}_{p^n}$ and $\mathcal{F}_x$ is the stalk of $\mathcal{F}$ at a geometric point $x$ over $\mathbb{F}_{p^n}$. If there is no ambiguity, we denote by $t_{\mathcal{F}}$ the trace function $t_{\mathcal{F},1}$. The main examples of trace functions we should keep in mind are the following:

(i) for any $f \in \mathbb{F}_p[T]$, consider the function $x \mapsto e(f(T)/p)$; this is the trace function attached to the Artin-Schreier sheaf $\mathcal{L}_{e(f/p)}$ (see [4, chapter 6, sections 1-3]);

(ii) the Birch sums $b \mapsto \text{Bi}(a, b; p)$ can be seen as the trace function attached to the sheaf $\text{FT}(\mathcal{L}_{e(aT^{(p-1)/p})})(\text{[17, 7.13, Sp-example (2)]});
(iii) the \( n \)-th HyperKloosterman sums: the map

\[
x \mapsto \text{Kl}_n(x; p) := \frac{(-1)^{n-1}}{p^{(n-1)/2}} \sum_{y_1, \ldots, y_n \in \mathbb{F}_p} e\left(\frac{y_1 + \cdots + y_n}{p}\right).
\]

can be seen as the trace function attached to the Kloosterman sheaf \( K\ell_n \) (see [18] for the definition of such a sheaf and for its basic properties).

**Definition 1.1.** [7, Definition 1.13] Let \( \mathcal{F} \) be a middle extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \) (see [17, 4-4.4.5]). The **conductor of** \( \mathcal{F} \) is defined to be

\[
c(\mathcal{F}) := \text{Rank}(\mathcal{F}) + |\text{Sing}(\mathcal{F})| + \sum_x \text{Swan}_x(\mathcal{F}),
\]

where:

(i) \( \text{Rank}(\mathcal{F}) = \dim \mathcal{F}_x \), for any \( x \) where \( \mathcal{F} \) is lisse;

(ii) \( \text{Sing}(\mathcal{F}) = \{ x \in \overline{\mathbb{F}}_p^1 : \mathcal{F} \text{ is not lisse at } x \} \);

(iii) \( \text{Swan}_x(\mathcal{F}) \) for \( x \in \overline{\mathbb{F}}_p^1 \) is the Swan conductor of \( \mathcal{F} \) at \( x \) (see [18, chapter 1] for the definition of the Swan conductor).

**Remark 1.** If \( \mathcal{F} \) is a middle extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \) of weight zero, then for any \( n \geq 1 \) and \( x \in \mathbb{F}_p^n \), one has that \( |t_{\mathcal{F},n}(x)| \leq \text{Rank}(\mathcal{F}) \leq c(\mathcal{F}) \), i.e., \( \|t\|_\infty \leq c(\mathcal{F}) \) ([5, lemma 1-8.1]).

The formalism of trace functions is very powerful, mainly for the following two reasons.

Firstly, because it is very flexible: the set of trace functions is closed under some basic operations such as sum, product, Fourier transform etc. Secondly, because once we have performed an operation, we can control the conductor of the output in terms of the conductors of the input data. Indeed, we have for example that:

(a) if \( \mathcal{F}, \mathcal{G} \) are middle-extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \), then \( \mathcal{F} \oplus \mathcal{G} \) and \( \mathcal{F} \otimes \mathcal{G} \) are still middle-extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \) (see for example [11, section 3-4]). Moreover \( t_{\mathcal{F} \oplus \mathcal{G},n}(x) = t_{\mathcal{F},n}(x) + t_{\mathcal{G},n}(x) \), and \( t_{\mathcal{F} \otimes \mathcal{G},n}(x) = t_{\mathcal{F},n}(x) \cdot t_{\mathcal{G},n}(x) \) for any \( n \geq 1 \) and any \( x \notin (\text{Sing}(\mathcal{F}) \cup \text{Sing}(\mathcal{G})) \cap \mathbb{F}_p^n \). Finally, \( c(\mathcal{F} \oplus \mathcal{G}) \leq c(\mathcal{F}) + c(\mathcal{G}) \), and \( c(\mathcal{F} \otimes \mathcal{G}) \leq 5c(\mathcal{F})^2 c(\mathcal{G})^2 \) ([6, pp. 6-7], [7, proposition 8-2]).

(b) Let \( \mathcal{F} \) be a middle-extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \), pure of weight 0 which is irreducible and not geometrically isomorphic to an Artin–Schreier sheaf of the form \( \mathcal{L}_{e(aT/p)} \) for some \( a \in \mathbb{F}_p \). Then there exists an irreducible middle-extension \( \ell \)-adic sheaf on \( \overline{\mathbb{A}}_{\mathbb{F}_p}^1 \), pure of weight 0, \( \mathcal{F}_{T_{e(T/p)}(\mathcal{F})} \), such that

\[
t_{\mathcal{F}_{T_{e(T/p)}(\mathcal{F})},n}(x) = \frac{1}{p^{n/2}} \sum_{y \in \mathbb{F}_p^n} t_{\mathcal{F},n}(y) e(\text{Tr}_{\mathbb{F}_p^n/\mathbb{F}_p}(xy) / p)
\]

for any \( n \geq 1 \) and \( x \in \mathbb{F}_p^n \). Moreover, \( c(\mathcal{F}_{T_{e(T/p)}(\mathcal{F})}) \leq 10c(\mathcal{F})^2 \) (see [18, chapters 5, 8] and [7, proposition 8-2]). In what follows we will denote \( \mathcal{F}_{T_{e(T/p)}(\mathcal{F})} = \mathcal{F}(\mathcal{F}) \) since there is not ambiguity;
On the size of the maximum of incomplete Kloosterman sums

Definition 1.2. [8, definition 1.2] Let $p$, $\ell > 2$ be two distinct primes and let $r \geqslant 1$ be an integer. A middle-extension $\ell$-adic sheaf, $\mathcal{F}$, is $r$-bountiful if

(i) $\mathcal{F}$ is pure of weight 0 and $\text{Rank}(\mathcal{F}) \geqslant 2$,
(ii) the geometric and arithmetic monodromy groups of $\mathcal{F}$ satisfy $G^{\text{arith}}_{\mathcal{F}} = G^{\text{geom}}_{\mathcal{F}}$, and $G^{\text{geom}}_{\mathcal{F}}$ is either $\text{Sp}_r(\mathbb{C})$ or $\text{SL}_r(\mathbb{C})$,
(iii) the projective automorphism group of $\mathcal{F}$

$$\text{Auto}_0(\mathcal{F}) := \{ \gamma \in \text{PGL}_2(\mathbb{F}_p) : \gamma^* \mathcal{F} \cong \mathcal{F} \otimes L \text{ for some rank 1 sheaf } L \}$$

is trivial.

Definition 1.3. Let $p$, $\ell > 2$ be two distinct primes and let $r \geqslant 1$ be an integer. A family of $\ell$-adic sheaves $(\mathcal{F}_a)_{a \in \mathbb{F}_p}$ is a 1-parameter family of sheaves of $\text{Sp}_{2g}$-type if the following conditions are satisfied:

(i) for any $a \in \mathbb{F}_p^\times$, $\mathcal{F}_a$ is an irreducible middle-extension $\ell$-adic Fourier sheaf on $\mathbb{A}_p^1$ which is pointwise pure of weight 0. We denote by $t_a$ the trace function attached to $\mathcal{F}_a$;
(ii) for any $a \in \mathbb{F}_p^\times$, the $\ell$-adic Fourier transform $\text{FT}(\mathcal{F}_a)$ is an $2g$-bountiful sheaf such that $G^{\text{geom}}_{\text{FT}(\mathcal{F}_a)} = \text{Sp}_{2g}(\mathbb{C})$;
(iii) for every $y \in \mathbb{F}_p$, there exists $\tau_y \in \text{PGL}_2(\mathbb{F}_p)$ such that $\tau_i \neq \tau_j$ if $i \neq j$ and

$$\hat{t}_a(y) = \hat{t}_1(\tau_y \cdot a)$$

for any $a \in \mathbb{F}_p^\times$, where $\hat{t}_a(\cdot)$ denotes the trace functions attached to $\text{FT}(\mathcal{F}_a)$.

Definition 1.4. Let $\ell$ be a prime number. A family $\mathfrak{F} = (\mathcal{F}_{a, p})_{a \in \mathbb{F}_p}$ is a bounded family of 1-parameter families of sheaves of $\text{Sp}_{2g}$-type if the following conditions hold:

(i) for any prime number $p \neq \ell$, the family $(\mathcal{F}_{a, p})_{a \in \mathbb{F}_p}$ is an 1-parameter family of sheaves of $\text{Sp}_{2g}$-type;
(ii) there exists $C \geqslant 1$ such that for any $p$ prime and $a \in \mathbb{F}_p^\times$

$$c(\mathcal{F}_{a, p}) \leqslant C.$$

We call the smallest $C$ with this property the conductor of the family and denote it by $c_{\mathfrak{F}}$.

Remark 2. The last two definitions are similar to [1, definitions 9.4, 9.5]

Definition 1.5. Let $\mathfrak{F}$ be a bounded family of 1-parameter families of $\text{Sp}_{2g}$-type. For any $A > 0$ we define

$$D_{\mathfrak{F}}(A) := \lim_{p \to \infty} \inf_{p \to \infty} \frac{1}{p-1} \left| \{ a \in \mathbb{F}_p^\times : M(t_{a, p}) > A \} \right|,$$
where we recall that
\[ M(t_{a,p}) = \max_{0 \leq H < p} \left| \frac{1}{\sqrt{p}} \sum_{0 \leq n < H} t_{a,p}(n) \right|. \]

**Example 1.1.** The following families are bounded families of 1-parameter families of \( \text{Sp}_2 \)-type:

(i) the family of Artin–Schreier sheaves \( \left( L_{e\left(\frac{ax + \nu}{p}\right)} \right)_{a \in \mathbb{F}_p^*} \). Indeed for any \( a \in \mathbb{F}_p^* \), \( L_{e\left(\frac{ax + \nu}{p}\right)} \) is a middle-extension \( \ell \)-adic Fourier sheaf that is pointwise pure of weight 0, with \( \text{cond}(L_{e\left(\frac{ax + \nu}{p}\right)}) = 2 \). Moreover, FT\( (L_{e\left(\frac{ax + \nu}{p}\right)}) = K\ell_2 \), the Kloosterman sheaf of rank 2 which is \( 2 \)-bountiful ([8, paragraph 3·2]), and
\[ \text{FT} \left( e \left( \frac{ax + \nu}{p} \right) \right) (y) = K\ell(a + \nu, 1; p), \]
so we can take \( \tau_y := \begin{pmatrix} 1 & y \\ 0 & 1 \end{pmatrix} \) in Definition 1·3;

(ii) the family of Artin–Schreier sheaves \( \left( L_{e\left(\frac{ax + \nu}{p}\right)} \right)_{b \in \mathbb{F}_p^*} \). It is enough to argue as above and to observe that
\[ \text{FT} \left( e \left( \frac{x + b\nu}{p} \right) \right) (y) = K\ell(b(y + 1), 1; p), \]
so we can take \( \tau_y := \begin{pmatrix} y + 1 & 0 \\ 0 & 1 \end{pmatrix} \) in Definition 1·3;

(iii) fix \( m \in \mathbb{Z} \). The family of Artin–Schreier sheaves \( \left( L_{e\left(\frac{ax + \nu}{p}\right)} \right)_{a \in \mathbb{F}_p^*} \) is a bounded family of 1-parameter families of \( \text{Sp}_2 \)-type. Also in this case one argues as above and observes that
\[ \text{FT} \left( e \left( \frac{ax + m\nu}{p} \right) \right) (y) = K\ell(my + m\nu, 1; p), \]
so we can take \( \tau_y := \begin{pmatrix} my & m \\ 1 & 0 \end{pmatrix} \) in Definition 1·3;

(iv) using similar arguments, one shows that the families
\[ \left( L_{e\left(\frac{ax + \nu}{p}\right)} \right)_{a \in \mathbb{F}_p^*}, \quad \left( L_{e\left(\frac{ax + \nu}{p}\right)} \right)_{b \in \mathbb{F}_p^*}, \quad \text{and} \quad \left( L_{e\left(\frac{ax + m\nu \nu}{p}\right)} \right)_{a \in \mathbb{F}_p^*} \]
are bounded families of 1-parameter families of \( \text{Sp}_2 \)-type.

Then Theorem 1·2 is a consequence of the following:

**Theorem 1·7.** Let \( 0 < \epsilon < 1 \). Let \( \mathcal{F} = (F_{a,p})_{a \in \mathbb{F}_p^*} \) be a bounded family of 1-parameter families of \( \text{Sp}_2 \)-type. For every prime \( p \) there exists \( S_{p,\epsilon} \subset \mathbb{F}_p^* \) such that:

(i) for any \( a \in S_{p,\epsilon} \),
\[ M(t_{a,p}) \geq \left( \frac{1 - \epsilon}{\sqrt{2\pi}} + o(1) \right) \log \log p; \]
(ii) \(|S_{p,\varepsilon}| \gg r, C_{\varepsilon} p^{-\frac{\log \ln p}{\log p}}\).

Similarly, Theorems 1.4 and 1.5 are a consequence of:

**Theorem 1.8.** Let \(\mathcal{F} = (F_{a,p})_{a \in \mathbb{F}_p^*} \) be a bounded family of 1-parameter families of \(\text{Sp}_2\)-type. There exist two constants and \(0 < c < 1 < C\) that depend only on \(c_{\mathcal{F}}\) such that for any fixed \(k \geq 1\),

\[
\left( (cg)^{2k} + o(1) \right) (\log k)^{2k} \leq \frac{1}{p-1} \sum_{a \in \mathbb{F}_p^*} M(t_{a,p})^{2k} \leq ((Ck)^{2k} + o(1)) (\log \log p)^{2k}.
\]

If, moreover, there exists \(\varepsilon > 0\) such that

\[
\left| \sum_{N \leq x \leq N+H} t_{a,p}(x) \right| \ll_{c_{\mathcal{F}}} H^{1-\varepsilon}
\]

uniformly for any \(1 < N < p\), \(p^{1/2-\varepsilon}/2 < H < p^{1/2+\varepsilon}/2\) and \(a \in \mathbb{F}_p^*\), then for any fixed \(k \geq 1\) one has

\[
\left( (cg)^{2k} + o(1) \right) (\log k)^{2k} \leq \frac{1}{p-1} \sum_{a \in \mathbb{F}_p^*} M(t_{a,p})^{2k} \leq (C2^k + o(1)) P(k),
\]

where \(P(k) = \exp(4k \log k + k \log \log k + o(k))\).

We then obtain:

**Corollary 1.9.** Under the same hypothesis as Theorem 1.8, we have that:

(i) for any \(A > 0\),

\[ D_{\mathcal{F}}(A) \geq \exp(-\exp(bA)), \]

where \(b > 0\) depends only on \(c_{\mathcal{F}}\);

(ii) if condition (1.7) holds, there exists a constant \(B > 0\) depending only on \(C_{\mathcal{F}}\) such that for \(A \to \infty\)

\[ D_{\mathcal{F}}(A) \leq \exp \left( -\exp \left( B A^{1/2-o(1)} \right) \right). \]

2. **Proof of Theorem 1.7**

2.1. **First step: Fourier expansion and Féjer Kernel**

The first step is to prove a quantitative version of the Fourier expansion for \((1/\sqrt{p}) \sum_{x \leq \alpha p} t(x)\).

**Lemma 2.1.** Let \(t : \mathbb{F}_p \to \mathbb{C}\) be a complex valued function on \(\mathbb{F}_p\). Then for any \(0 < \alpha \leq 1\) and \(1 \leq N \leq p\) we have

\[
\frac{1}{\sqrt{p}} \sum_{x \leq \alpha p} t(x) = -\frac{1}{2\pi i} \sum_{1 \leq |n| \leq N} \hat{t}(n) \left( 1 - e(-an) \right) + \alpha \hat{t}(0) + O \left( \frac{\|t\|_\infty \sqrt{p} \log p}{N} \right),
\]

where the implied constant is absolute.
Remark 3. In the case where \( t = \chi \) is a multiplicative character, we recover [25] (and indeed the proof of Lemma 2.1 closely follows the one in [25]). The result in [25] has been extensively used in many works on the maximum of incomplete character sums, such as [2, 12–14, 23, 24, 26] among others.

Proof. Let us introduce the function

\[
\Phi_\alpha(s) = \begin{cases} 
1 & \text{if } 0 < s < 2\pi\alpha, \\
\frac{1}{2} & \text{if } s = 0 \text{ or } s = 2\pi\alpha, \\
0 & \text{if } 2\pi\alpha < s < 2\pi.
\end{cases}
\]

Then the Fourier series of \( \Phi_\alpha \) is

\[
\Phi_\alpha(s) = \alpha + \sum_{n > 0} \frac{\sin(2\pi\alpha n)}{\pi n} \cos(ns) - \frac{\cos(2\pi\alpha n - 1)}{n\pi} \sin(ns)
\]

\[
= \alpha + \frac{1}{\pi} T(s) - \frac{1}{\pi} T(s - 2\pi\alpha),
\]

where

\[
T(x) := \sum_{n > 0} \frac{\sin(nx)}{n}.
\]

Observe that for any \( N > 1 \) one has

\[
T(x) = \sum_{0 < n \leq N} \frac{\sin(nx)}{n} + R_N(x),
\]

with \( R_N(0) = R_N(\pi) \), \( R_N(2\pi - x) = -R_N(x) \) and \( R_N(x) = O(1/(N x)) \) for any \( x \in (0, \pi) \) [25, equation 10]. It follows that

\[
\frac{1}{\sqrt{p}} \sum_{x \leq \alpha p} t(x) = \frac{1}{\sqrt{p}} \sum_{x < p} t(x) \Phi_\alpha\left(\frac{2\pi x}{p}\right) + O(\|t\|_\infty / \sqrt{p})
\]

\[
= \frac{1}{\sqrt{p}} \sum_{x < p} t(x) \left( \alpha + \frac{1}{\pi} T\left(\frac{2\pi x}{p}\right) - \frac{1}{\pi} T\left(\frac{2\pi x}{p} - 2\pi\alpha\right) \right) + O\left( \frac{\|t\|_\infty}{\sqrt{p}} \right)
\]

\[
= \frac{1}{\sqrt{p}} \sum_{x < p} t(x) \left( \alpha + \frac{1}{\pi} \sum_{0 < n \leq N} \frac{\sin\left(\frac{2\pi n x}{p}\right)}{n} + \frac{1}{\pi} R_N\left(\frac{2\pi x}{p}\right) \right)
\]

\[
- \frac{1}{\pi} \sum_{0 < n \leq N} \frac{\sin\left(\frac{2\pi n x}{p} - 2\pi\alpha n\right)}{n} + \frac{1}{\pi} R_N\left(\frac{2\pi x}{p} - 2\pi\alpha\right) + O\left( \frac{\|t\|_\infty}{\sqrt{p}} \right)
\]

\[
= \frac{1}{\sqrt{p}} \sum_{x < p} t(x) \left( \frac{1}{\pi} \sum_{0 < n \leq N} \frac{\sin\left(\frac{2\pi n x}{p}\right)}{n} - \frac{1}{\pi} \sum_{0 < n \leq N} \frac{\sin\left(\frac{2\pi n x}{p} - 2\pi\alpha n\right)}{n} \right)
\]

\[
+ \alpha \hat{t}(0) + O\left( \frac{\|t\|_\infty \sqrt{p \log p}}{N} \right).
\]
On the other hand, we have
\[
\sin \left( \frac{2\pi nx}{p} \right) = e^{\left( \frac{nx}{p} \right)} - e^{\left( -\frac{nx}{p} \right)}, \quad \sin \left( \frac{2\pi nx}{p} - 2\pi \alpha \right) = e^{\left( \frac{nx}{p} - \alpha n \right)} - e^{\left( -\frac{nx}{p} - \alpha n \right)}.
\]

Then,
\[
\frac{1}{\sqrt{p}} \sum_{x \in \mathbb{F}_p} t(x) \left( \frac{e^{\left( \frac{nx}{p} \right)} - e^{\left( -\frac{nx}{p} \right)}}{2i} \right) = -\frac{1}{2i} (\hat{t}(n) - \hat{t}(-n)),
\]
and similarly
\[
\frac{1}{\sqrt{p}} \sum_{x \in \mathbb{F}_p} t(x) \left( \frac{e^{\left( \frac{nx}{p} - \alpha n \right)} - e^{\left( -\frac{nx}{p} - \alpha n \right)}}{2i} \right) = -\frac{1}{2i} (e(-\alpha n)\hat{t}(n) - e(\alpha n)\hat{t}(-n)).
\]

Now we use the strategy of [26], introducing the Fejér kernel:

**Lemma 2.2.** For any \( t : \mathbb{F}_p \to \mathbb{C}, \)

\[
M(t) \geq \max_{a \in [0, 1]} \left| \frac{1}{4\pi} \sum_{1 \leq |n| < N} \frac{\hat{t}(n)}{n} (1 - e(-\alpha n)) \right| + O \left( \| \hat{t} \|_\infty \right).
\]

**Proof.** The quantitative version of the Fourier transform (Lemma 2.1) leads to

\[
\frac{1}{\sqrt{p}} \sum_{x \leq \alpha p} t(x) = -\frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{t}(n)}{n} (1 - e(-\alpha n)) + a\hat{t}(0) + O(1)
\]
\[
= -\frac{1}{2\pi i} \sum_{1 \leq |n| < p} \frac{\hat{t}(n)}{n} (1 - e(-\alpha n)) + O \left( \| \hat{t} \|_\infty \right).
\]

We now extend the outer sum to all values modulo \( p \) using the Fejér kernel: for any \( 1 < N < p, \) we have

\[
\frac{1}{2\pi i} \sum_{1 \leq |n| \leq N} \frac{\hat{t}(n)}{n} (1 - e(-\alpha n)) = \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{t}(n)}{n} (1 - e(-\alpha n)) \cdot
\]
\[
\sum_{1 < |a| \leq N} \phi(a) \int_0^1 e((a - n)\vartheta) d\vartheta + O \left( \| \hat{t} \|_\infty \right) \quad (2.1)
\]
\[
= \int_0^1 A(\vartheta) \Phi_N(\vartheta) d\vartheta + O \left( \| \hat{t} \|_\infty \right),
\]
where

\[
\phi(a) := 1 - \frac{|a|}{N}, \quad \Phi_N(\vartheta) := \sum_{|a| \leq N} \phi(a) e(a\vartheta) = \frac{1}{N} \left( \frac{\sin \frac{N\vartheta}{2}}{\sin \frac{\vartheta}{2}} \right)^2 \quad (2.2)
\]
is the Féjer Kernel, and

\[ A(\vartheta) := \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{i}(n)}{n} (1 - e(-\alpha n))e(-\vartheta n) = \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{i}(n)}{n} (e(-\vartheta n) - 1 + 1 - e(- (\vartheta + \alpha) n)) \]

\[ - \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{i}(n)}{n} (e(-\vartheta n) - 1) + \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{i}(n)}{n} (1 - e(- (\vartheta + \alpha) n)). \]

By the triangle inequality,

\[ \max_{\vartheta \in [0,1]} |A(\vartheta)| \leq 2 \max_{\vartheta \in [0,1]} \left| \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p} \frac{\hat{i}(n)}{n} (1 - e(-\alpha n)) \right| \]

\[ \leq 2 \max_{\vartheta \in [0,1]} \left| \frac{1}{\sqrt{p}} \sum_{x \leq \alpha p} t(x) \right| + O(\|t\|_\infty) \]

\[ \leq 2M(t) + O(\|t\|_\infty). \]

Thus, we get

\[ \left| \frac{1}{4\pi i} \sum_{1 \leq |n| \leq N} \frac{\hat{i}(n)}{n} (1 - e(-\alpha n)) \right| \leq (M(t) + O(\|t\|_\infty)) \cdot \int_{0}^{1} \Phi_N(\vartheta) d\vartheta. \tag{2.3} \]

Using the fact that \( \int_{0}^{1} \Phi_N(\vartheta) d\vartheta = 1 \), we conclude the proof.

To conclude the proof of Theorem 1.7, it is sufficient to prove the following generalisation of Proposition 1.3:

**Proposition 2.3.** For any prime \( p \), let \( K \) be the trace function attached to an irreducible 2-bountiful sheaf \( \mathcal{K} \) on \( \mathbb{A}_p^1 \). Fix \( 0 < \varepsilon < 1 \). For every \( 1 \leq |n| \leq (\log p)^{1-\varepsilon} \), let \( \tau_n \in \text{PGL}_2(\mathbb{F}_p) \) such that \( \tau_n \neq \tau_m \) if \( n \neq m \). Then there exists \( S_{p,\varepsilon} \subset \mathbb{P}_p^\times \) such that for any \( a \in S_{p,\varepsilon} \)

\[ K(\tau_n \cdot a) \geq \sqrt{2} \]

for any \( 1 \leq n \leq (\log p)^{1-\varepsilon} \), and

\[ K(\tau_n \cdot a) \leq -\sqrt{2} \]

for any \(- (\log p)^{1-\varepsilon} \leq n \leq -1 \). Moreover \( |S_{p,\varepsilon}| \gg_{\varepsilon, c(\mathcal{K})} p^{1- \frac{\log 16}{\log p}} \).

**Remark 4.** Since \( \text{Sp}_2(\mathbb{C}) = \text{SL}_2(\mathbb{C}) \), when considering a 2-bountiful sheaf \( \mathcal{K} \) there is no need to specify the monodromy groups of \( \mathcal{K} \).

Assuming this Proposition, whose proof is to be found in the next section, we prove Theorem 1.7. Applying Lemma 2.2 for \( t = t_{a,p} \), and using the fact that \( \|\hat{t}_{a,p}\|_\infty \leq c(\text{FT}(\mathcal{F}_{a,p})) \leq 10c(\mathcal{F}_{a,p})^2 \leq 10c^2_{\delta} \) (see Remark 1 and [7, proposition 8.2]), we get
\[ M(t_{a,p}) = \max_{a \in [0,1]} \left| \frac{1}{\sqrt{p}} \sum_{x \leq ap} t_{a,p}(x) \right| \]
\[ \geq 1 \frac{\max_{a \in [0,1], 1 \leq n < p} \sum_{1 \leq |n| \leq N} \frac{\hat{t}_{a,p}(n)}{n} (1 - e(-\alpha n)) + O_{c(\beta)}(1)}{4\pi} \]
\[ = 1 \frac{\max_{a \in [0,1], 1 \leq n < p} \sum_{1 \leq |n| \leq N} \frac{\hat{t}_{1,p}(\tau_n \cdot a)}{n} (1 - e(-\alpha n)) + O_{c(\beta)}(1)}{4\pi} \]
\[ \geq 1 \frac{\max_{a \in [0,1], 1 \leq n < p} \sum_{1 \leq |n| \leq (\log p)^{1-\varepsilon}} \frac{\hat{t}_{1,p}(\tau_n \cdot a)}{n} (1 + (-1)^{n+1}) + O_{c(\beta)}(1)}{4\pi} \]

where the second step uses the fact that \( \hat{t}_{a,p}(n) = \hat{t}_{1,p}(\tau_n \cdot a) \) (property (iii) in Definition 1.3). Applying Proposition 2.3 to \( K = \hat{t}_{1,p} \), there exists \( S_{p,\varepsilon} \subset \mathbb{F}_p^\times \) such that for any \( a \in S_{p,\varepsilon} \)
\[ M(t_{a,p}) \geq \frac{2\sqrt{2}}{4\pi} \sum_{1 \leq |n| \leq (\log p)^{1-\varepsilon} \atop n \equiv 1(2)} \frac{1}{n} + O_{c(\beta)}(1) \geq \left( \frac{1}{\sqrt{2\pi}} + o(1) \right) \log \log p, \]

and this concludes the proof of Theorem 1.7.

2.2. Preliminaries for the proof of Proposition 2.3: Chebyshev polynomials

Consider an irreducible 2-bountiful sheaf \( \mathcal{K} \) on \( \mathbb{A}^1_{\mathbb{Q}} \), and denote the trace function attached to it by \( K(\cdot, r) = t_{\mathcal{K},r}(\cdot) \), where \( K(\cdot) = K(\cdot, 1) \) if there is no ambiguity. Combining the fact that \( G^K_{\text{geom}} = G^K_{\text{arith}} = \text{SL}_2(\mathbb{C}) \) (property (ii) in the definition of 2-bountiful) together with Deligne’s Equidistribution Theorem ([18, chapter 3]), it follows that for any \( r \geq 1 \), and \( a \in \mathbb{F}_p^\times \) one has
\[ K(a, r) = 2 \cos(\theta(a, r)) \tag{2.4} \]

with \( \theta(a, r) \in [0, \pi] \), and that when \( r \to \infty \) the angles \( \{\theta(a, r) : a \in \mathbb{F}_p^\times\} \) equidistribute in the interval \( [0, \pi] \) with respect to the pushforward of the Haar measure of \( \text{SU}_2(\mathbb{C}) \subset \text{SL}_2(\mathbb{C}) \), which is the Sato–Tate measure \( \mu_{\text{ST}} = (2/\pi) \int \sin^2 d\theta \) ([18, chapter 13]). Moreover, for any \( n \geq 1 \) one can consider the the middle-extension \( \ell \)-adic sheaf \( \text{Sym}^n \mathcal{K} \). Then, for any \( r \geq 1 \) and \( a \in \mathbb{F}_p^\times \) one has that
\[ t_{\text{Sym}^n \mathcal{K}, r}(a) = \frac{\sin((n + 1)\theta(a, r))}{\sin(\theta(a, r))} = U_n(K(a, r)), \]

where the angles \( \theta(a, r) \) are the same as in (2.4) and \( U(n) \in \mathbb{Z}[\theta] \) (see [18, chapters 3, 13] for a discussion on the sheaf \( \text{Sym}^n \mathcal{K} \)). In terms of representation theory, the polynomials \( U_n \) are all the irreducible characters of \( \text{SU}_2(\mathbb{C}) \). In particular, by the Peter–Weyl Theorem, these polynomials form an orthonormal basis of \( L^2([0, \pi], \mu_{\text{ST}}) \). Finally, we call a trigonometric polynomial of degree \( s \geq 0 \) any \( Y \in L^2([0, \pi], \mu_{\text{ST}}) \) of the form
\[ Y = \sum_{j=0}^{s} y(j)U_j, \tag{2.5} \]

with \( y(s) \neq 0 \). We refer to \( s \) as the Chebyshev degree of \( Y \).
Remark 5. Let \( f \in L^2([0, \pi], \mu_{ST}) \). We can decompose \( f \) using the orthonormal basis \( \{U_n\}_n \), i.e. we can write \( f \) as

\[
 f = \sum_n a_n U_n, \tag{2.6}
\]

where

\[
a_n = \int_0^\pi f(\theta) U_n(\theta) d\mu_{ST}.
\]

The decomposition (2.6) is called the Chebyshev expansion of \( f \).

Let us begin by proving some properties of the sheaf \( \text{Sym}^n(K) \).

**Lemma 2.4.** Let \( K \) as above. For any \( n > 0 \):

(i) the geometric monodromy group of \( \text{Sym}^n(K) \) is given by

\[
 G_{\text{Sym}^n(K)}^{\text{geom}} \cong \begin{cases} 
 \text{SL}_2(\mathbb{C}) & \text{if } n \text{ is odd}, \\
 \text{PSL}_2(\mathbb{C}) & \text{if } n \text{ is even};
\end{cases}
\]

(ii) the projective automorphism group

\[
 \text{Aut}_0(\text{Sym}^n(K)) = \{ \gamma \in \text{PGL}_2(\mathbb{F}_p) : \gamma^* \text{Sym}^n(K) \cong \text{Sym}^n(K) \otimes \mathcal{L} \}
\]

is trivial;

(iii) the conductor of \( \text{Sym}^n(K) \) is bounded by

\[
 c(\text{Sym}^n(K)) \leq n \cdot c(K);
\]

(iv) if \( n_1 \neq n_2 \), then \( \text{Sym}^{n_1}(K) \not\cong \text{Sym}^{n_2}(K) \otimes \mathcal{L} \) for any rank one sheaf \( \mathcal{L} \).

**Proof.** For part (i), recall that by definition of the geometric monodromy group, \( G_{\text{Sym}^n(K)}^{\text{geom}} = \text{Sym}^n(G_{K}^{\text{geom}}) \). Then the result follows since \( G_{K}^{\text{geom}} = \text{SL}_2(\mathbb{C}) \) by hypothesis. For part (ii), let \( \gamma \in \text{PGL}_2(\mathbb{F}_p) \). First observe that for any \( r \geq 1 \), and \( x \in \mathbb{F}_p^{r} \), we have that

\[
 t_{\text{Sym}^n(K), r}(x) = \frac{\sin((n + 1)\theta(x, r))}{\sin(\theta(x, r))}, \quad t_{\gamma^* \text{Sym}^n(K), r}(x) = \frac{\sin((n + 1)\theta(\gamma \cdot x, r))}{\sin(\theta(\gamma \cdot x, r))},
\]

where \( \theta(x, r) \) is as in (2.4). By contradiction, assume that \( \gamma^* \text{Sym}^n(K) \cong \text{Sym}^n(K) \otimes \mathcal{L} \) for some rank one sheaf, and let \( U \subset \overline{A}_{\mathbb{F}_p}^1 \) be a dense open set where \( \gamma^* \text{Sym}^n(K) \), \( \text{Sym}^n(K) \) and \( \mathcal{L} \) are all lisse. Then for any \( x \in U(\mathbb{F}_p^{r}) \),

\[
 t_{\gamma^* \text{Sym}^n(K), r}(x) = t_{\text{Sym}^n(K) \otimes \mathcal{L}, r}(x) = t_{\text{Sym}^n(K), r}(x) \cdot t_{\mathcal{L}, r}(x).
\]

On the other hand, \( \gamma^* \text{Sym}^n(K) \) and \( \text{Sym}^n(K) \) are pure of weight 0, and therefore \( \mathcal{L} \) is pure of weight 0, i.e. we have that \( |t_{\mathcal{L}, r}(x)| = 1 \) for any \( r \geq 1 \) and \( x \in U(\mathbb{F}_p^{r}) \). It follows that for any \( x \in U(\mathbb{F}_p^{r}) \)

\[
 |t_{\gamma^* \text{Sym}^n(K), r}(x)| = |t_{\text{Sym}^n(K), r}(x)|.
\]

\[
 |t_{\gamma^* \text{Sym}^n(K), r}(x)| = |t_{\text{Sym}^n(K), r}(x)|.
\]
Due to the fact that $\mathcal{K}$ is a bountiful sheaf, an application of the Goursat–Kolchin–Ribet criterion as stated in [8, lemma 2.4] combined with Deligne’s equidistribution Theorem ([5, section 3.5]) implies that the angles $(\theta(x, r), \theta(y \cdot x, r)) : x \in \mathbb{F}_p^r$ become equidistributed in $([0, \pi] \times [0, \pi], \mu_{ST} \otimes \mu_{ST})$ as $r \to \infty$. Now consider

$$
\Theta_1 = \left\{ \theta \in [0, \pi] : \left| \frac{\sin((n+1)\theta)}{\sin(\theta)} \right| < \frac{3}{4} \right\}, \quad \Theta_2 = \left\{ \theta \in [0, \pi] : \left| \frac{\sin((n+1)\theta)}{\sin(\theta)} \right| > \frac{3}{4} \right\}.
$$

It easy to see that $\Theta_1$, $\Theta_2$ are non empty open subsets of $[0, \pi]$. Then we have that

$$
|[x \in \mathbb{F}_p^r : (\theta(x, r), \theta(y \cdot x, r)) \in \Theta_1 \times \Theta_2]| \quad \mu_{ST}(\Theta_1) \cdot \mu_{ST}(\Theta_2) > 0,
$$

when $r \to \infty$. Hence, for $r$ large enough, we can find $x \in U(\mathbb{F}_p^r)$ such that

$$
|t_{Sym^n(\mathcal{K}), r}(x)| < 1/4, \quad |t_{r^* \cdot Sym^n(\mathcal{K}), r}(x)| > 3/4.
$$

But this contradicts (2.7). The proof of part (iii) is included in the proof of Deligne’s Equidistribution Theorem (see for example [18, paragraph 3.6]). For part $(iv)$, it is enough to observe that the sheaves $\text{Sym}^{n_1}(\mathcal{K})$ and $\text{Sym}^{n_2}(\mathcal{K})$ are irreducible (see [11, p. 155]) and that $\text{Rank}(\text{Sym}^{n_1}(\mathcal{K})) = n_1 + 1$, while $\text{Rank}(\text{Sym}^{n_2}(\mathcal{K}) \otimes \mathcal{L}) = \text{Rank}(\text{Sym}^{n_2}(\mathcal{K})) = n_2 + 1$.

**Lemma 2.5.** Let $d \geq 0$. Let $(Y_i)_{i=0}^d$ be a family of trigonometric polynomials

$$
Y_i = \sum_{j=0}^{\deg Y_i} y_i(j) U_j
$$

such that $\deg Y_i \leq d$ for all $i$, and let $(\tau_i)_{i=1}^n \in \text{PGL}_2(\mathbb{F}_p)^n$ be such that $\tau_i \neq \tau_j$ for $i \neq j$ then

$$
\left| \sum_{a \in \mathbb{F}_p} \prod_{i=0}^n Y_i(\theta(\tau_i \cdot a)) - p \prod_{i=0}^n y_i(0) \right| \leq 10 \cdot c(\mathcal{K})^2 d^{2n+2} y^n \sqrt{p},
$$

where $y = \max_{i,j} |y_i(j)|$.

**Proof.** It is enough to study

$$
S = \sum_{a \in \mathbb{F}_p} \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a)),
$$

for any $n_i \geq 0$, by following the proof of [8, proposition 1.1] and [27, proposition 4.1]. Let us denote by $\mathcal{F} = \bigotimes_i \tau_i^* \text{Sym}^{n_i}(\mathcal{K})$ and let $U \subset \mathbb{A}_F^1_{\mathbb{F}_p}$ be the largest open subset on which $\mathcal{F}$ is lisse. Notice that $t_\mathcal{F}(a) = \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a))$ for any $a \in U(\mathbb{F}_p)$. Then

$$
|S - \sum_{a \in U(\mathbb{F}_p)} \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a))| \leq \sum_i c(\tau_i^* \text{Sym}^{n_i}(\mathcal{K}))
$$

since all the sheaves are pure of weight 0. On the other hand, the Grothendieck–Lefschetz formula gives

$$
\sum_{a \in U(\mathbb{F}_p)} \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a)) = \sum_{i=0}^2 (-1)^i \text{Tr}(\text{Fr} | H^i(U, \mathcal{F})).
$$
Since $\mathcal{F}$ is a middle-extension sheaf (as the product of middle-extension sheaves is a middle-extension sheaf), it follows that $H^0_{c}(U, F) = 0$. Moreover, according to parts (iii),(iv) to Lemma 2.4 and the discussion in [8, paragraph 3.1] we have that the $(n + 1)$-tuple $\{\tau_i^* \text{Sym}^n_i(K)\}_{i=0}^n$ is a strictly $U$-generous in the sense of [8, definition 2.1]. Thus, we may use [8, theorem 2.7] to obtain

$$\dim(H^2_{c}(U, F)) = \prod_{i=0}^n M_{n_i},$$

where $M_{n_i} := \text{Mult}(1, \text{Sym}^n_i \text{Std})$ is the multiplicity of the standard representation of $\text{SL}_2(\mathbb{C})$, Std, in $\text{Sym}^n_i \text{Std}$. On the other hand, $\text{Sym}^n_i \text{Std}$ is irreducible for any $n_i$, and it is trivial if and only if $n_i = 0$. Thus, we have that

$$M_{n_i} = \begin{cases} 1 & \text{if } n_i = 0, \\ 0 & \text{otherwise.} \end{cases} \quad (2.9)$$

Hence,

$$\left| \sum_{a \in U(\mathbb{F}_p)} \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a)) - p \prod_{i=0}^n M_{n_i} \right| = |\text{Tr}(\text{Fr} | H^1_{c}(U, F))| \leq \dim(H^1_{c}(U, F)) \sqrt{p},$$

by the Riemann Hypothesis over finite fields ([5]). It remains to bound $\dim(H^1_{c}(U, F))$. We start by applying the Euler-Poincaré formula, obtaining

$$\dim(H^1_{c}(U, F)) = (2 - (\text{Sing} \mathcal{F})) \text{Rank}(\mathcal{F}) + \sum_{x \in \mathbb{P}^1_{\mathbb{F}_p}} \text{Swan}_x(\mathcal{F}) + \dim(H^2_{c}(U, F))$$

$$\leq (2 - (\text{Sing} \mathcal{F})) \text{Rank}(\mathcal{F}) + \sum_{x \in \mathbb{P}^1_{\mathbb{F}_p}} \text{Swan}_x(\mathcal{F}) + 1,$$

by (2.9). It is shown in [7, proposition 8.2] that

$$\text{Rank}(\mathcal{F}) = \prod_i \text{Rank}(\tau_i^* \text{Sym}^n_i(K)) = \prod_i \text{Rank}(\text{Sym}^n_i(K)) \leq \max_{i} (\text{Rank}(\text{Sym}^n_i(K)))^n$$

and that

$$|\text{Sing}(\mathcal{F})| \leq \sum_i |\text{Sing}(\tau_i^* \text{Sym}^n_i(K))| \leq n \max_{i} (c(\text{Sym}^n_i(K))).$$

Let us compute $\text{Swan}_x(\mathcal{F})$ for every $x \in \mathbb{P}^1_{\mathbb{F}_p}$. For any $i$, let $\lambda_i(x)$ be the largest break of $\text{Sym}^n_i(K)$ at $x$ and let $\lambda_x$ be the largest break of $\mathcal{F}$ at $x$. Using [18, lemma 1.3], we get that

$$\lambda(x) \leq \max_{i} \lambda_i(x).$$

Hence,

$$\text{Swan}_x(\mathcal{F}) \leq \text{Rank}(\mathcal{F}) \cdot \lambda_x(\mathcal{F}) \leq \max_{i} (\text{Rank}(\text{Sym}^n_i(K)))^n \cdot \max_{i} (c(\text{Sym}^n_i(K))).$$
and therefore
\[
\dim(H^1_c(U, \mathcal{F})) \leq \text{Rank}(\mathcal{F}) \cdot \text{Sing} \mathcal{F} + |\text{Sing}(\mathcal{F})| \cdot \max_i \text{Swan}_x(\mathcal{F}) \\
\leq 10n \cdot (\max_i \text{Rank}(\text{Sym}^{n_i}(\mathcal{K})))^n \cdot (\max_i c(\text{Sym}^{n_i}(\mathcal{K})))^2.
\]

Putting it all together, we get that
\[
\left| \sum_{a \in U(\mathbb{F}_p)} \prod_{i=0}^n U_{n_i}(K(\tau_i \cdot a)) - p \prod_{i=0}^n M_{n_i} \right| = |\text{Tr}(\text{Fr} | H^1_c(U, \mathcal{F})) | \leq L \sqrt{p},
\]
where \( L = 10n \cdot (\max_i \text{Rank}(\text{Sym}^{n_i}(\mathcal{K})))^n \cdot (\max_i c(\text{Sym}^{n_i}(\mathcal{K})))^2. \) And otherwise, if there exists an \( i \) for which \( n_i \neq 0 \), we have
\[
|S| \leq L \sqrt{p}.
\]

The result then follows from the fact that
\[
\text{Rank}(\text{Sym}^{n_i}(\mathcal{K})) = n_i + 1 < 2d, \quad \text{and} \quad c(\text{Sym}^{n_i}(\mathcal{K})) \leq n_i c(\mathcal{K}) \leq dc(\mathcal{K}),
\]
because \( n_i \leq d \) for every \( i \) by assumption.

2.3. Proof of Proposition 2.3

Fix \( m, \gamma \in \mathbb{N} \). To each \( a \in \mathbb{F}_p^m \) we associate a point in \([0, \pi]^{2m}\) by defining
\[
\theta(a) = (\theta(\tau_{-m}a), \cdots, \theta(\tau_{-1}a), \theta(\tau_1a), \cdots, \theta(\tau_m a)),
\]
where \( \theta(\tau_i \cdot a) \) is the angle associated to \( K(\tau_i \cdot a) \) accordingly with Section 2.2. Moreover, we denote by \( \chi^\pm_i(\cdot) \) (resp. \( \chi^\pm_i(\cdot) \)) the characteristic function of the interval \([0, \pi/2 - \pi/\gamma] \) (resp.\([\pi/2 + \pi/\gamma, \pi]\)). To prove Proposition 2.3, we start by approximating the values of the product
\[
\prod_{i=1}^m \chi^+_\frac{\pi}{\gamma}(\theta(\tau_i \cdot a)) \prod_{i=1}^m \chi^-\frac{\pi}{\gamma}(\theta(\tau_{-i} \cdot a))
\]
using Chebyshev polynomials. We use the same method adopted in [20, section 3]: for any \( m \), we find an integer \( L \equiv -1 \pmod{2\gamma} \) and two families of trigonometric polynomials \( \{\alpha_{L,i}\} \) and \( \{\beta_{L,i}\} \) such that for
\[
A_L \left( \frac{\theta(a)}{\pi} \right) = \prod_{1 \leq |i| \leq m} \alpha_{L,i} \left( \frac{\theta(\tau_i \cdot a)}{\pi} \right),
\]
\[
B_L \left( \frac{\theta(a)}{\pi} \right) = \sum_{1 \leq |i| \leq m} \beta_{L,i} \left( \frac{\theta(\tau_i \cdot a)}{\pi} \right) \prod_{j \neq i} \alpha_{L,j} \left( \frac{\theta(\tau_j \cdot a)}{\pi} \right),
\]
the following inequality holds for any \( a \in \mathbb{F}_p \)
\[
A_L \left( \frac{\theta(a)}{\pi} \right) - B_L \left( \frac{\theta(a)}{\pi} \right) \leq \prod_{i=1}^m \chi^+_\frac{\pi}{\gamma}(\theta(\tau_i \cdot a)) \prod_{i=1}^m \chi^-\frac{\pi}{\gamma}(\theta(\tau_{-i} \cdot a)). \tag{2.10}
\]
Moreover, this approximation satisfies the following properties.
Lemma 2.6. With the notations above, we have:

(i) there exist two constants \( L_0 \geq 1 \) and \( c > 0 \) depending only on \( \gamma \), such that the contribution \( \Delta \) of the constant term in the Chebyshev expansions of \( A_L(\theta/\pi) - B_L(\theta/\pi) \) satisfies:

\[
\Delta \geq \frac{1}{2} \left( \frac{1}{2} - \frac{1}{\gamma} \right)^{2m}.
\]

when \( L \) is the smallest integer such that \( L \equiv -1 \mod 2\gamma \) and \( L \geq \max(cm, L_0) \);

(ii) All the coefficients in the Chebyshev expansion (see Remark 5) of the factors in \( A_L(\theta/\pi) \) and all the terms in \( B_L(\theta/\pi) \) are bounded by 1.

(iii) The Chebyshev degree of the factors of \( A_L(\theta/\pi) \) and \( B_L(\theta/\pi) \) are \( \leq 2L \).

Assuming this Lemma, we can easily prove Proposition 2.3. Fix \( \gamma = 1/4 \) in Lemma 2.6 and denote

\[
S_{p,m} := \{ a \in \mathbb{F}_p^\times : K(\tau_n \cdot a) \geq \sqrt{2}, K(\tau_{-n} \cdot a) \leq -\sqrt{2} \text{ for any } n = 1, \ldots, m \}.
\]

Notice that \( a \in S_{p,m} \) if and only if \( \theta(a) \in [-\frac{\pi}{2}, -\frac{\pi}{4}]^m \times [0, \frac{\pi}{4}]^m \). Let \( L \) be as in part (i) of Lemma 2.6; then

\[
|S_{p,m}| = \sum_{a \in \mathbb{F}_p^\times} \prod_{i=1}^m \chi_{\frac{1}{4}}(\theta(\tau_i \cdot a)) \prod_{i=1}^m \chi_{-\frac{1}{4}}(\theta(\tau_{-i} \cdot a))
\]

\[
\geq \sum_{a \in \mathbb{F}_p^\times} \left( A_L \left( \frac{\theta(a)}{\pi} \right) - B_L \left( \frac{\theta(a)}{\pi} \right) \right)
\]

\[
= p \Delta + O(mc(K)^2L^{4m+2}\sqrt{p})
\]

\[
\geq \frac{1}{2} \left( \frac{1}{4} \right)^{2m} p + O(mc(K)^2L^{4m+2}\sqrt{p}),
\]

where in the second step we use Lemma 2.5. Also notice that:

(i) the condition \( \tau_i \neq \tau_j \) for \( i \neq j \) is satisfied by definition of 1-parameter family;

(ii) by part (ii) of Lemma 2.6 we have that \( \eta \) in Lemma 2.5 is equal to 1.

Let us denote \( \delta = 1 - \varepsilon \) and consider \( m = \lfloor (\log p)^\delta \rfloor \). By part (i) of Lemma 2.6 we know that \( \max(cm, L_0) \leq L \leq \max(2\gamma cm, L_0) \). We may assume \( cm \leq L \leq 2\gamma cm \), because \( L_0 \) is an absolute constant (it depends only on \( \gamma = 1/4 \)). Then

\[
mc(K)^2L^{2m+2}\sqrt{p} \leq 2(\log p)^\delta c(K)^2(2\gamma c(\log p)^\delta)^4(\log p)^{2\delta+2}\sqrt{p}
\]

\[
= o((\log p)^{10\delta}(\log p)^{\delta})
\]

\[
= o(p^{\frac{1}{2}+\eta}),
\]

for any \( \eta > 0 \). On the other hand, we have

\[
\left( \frac{1}{4} \right)^{2m} = e^{-\log 16(\log p)^\delta} = e^{-\log 16 \log p^\delta} = p^{\frac{\log 16}{\log p^\delta}}.
\]
Thus, we obtain
\[ |S_{p,[(\log p)\gamma]}| \gg e \cdot p^{\frac{\log 16}{\log p}} , \]
as we desired.

**Proof of Lemma 2.6.** The proof utilises ideas from [20, lemma 3.2] and [3]. Let \( x := (x_{-m}, \ldots, x_{-1}, x_{1}, \ldots, x_{m}) \in [0, 1]^{2m} \). We first construct the polynomial \( A_L(x) \). Since
\[ A_L(x) = \prod_{1 \leq |i| \leq m} \alpha_{L,i} \left( x_i \right) , \]
it is sufficient to define the \( \alpha_{L,i} \)s:

(i) if \( 1 \leq i \leq m \), \( \alpha_{L,i} \) is a trigonometric polynomial in one variable
\[ \sum_{|\ell| \leq L} \hat{\alpha}_{L,+}(\ell) e(\ell x) , \]
where the \( \hat{\alpha}_{L,+}(\ell) \)s are defined as in [3, (2.2), lemma 5, (2.17)] with \( u = 0 \), \( v = 1/2 - 1/\gamma \);

(ii) if \( -m \leq i \leq 1 \), \( \alpha_{L,i} \) is a trigonometric polynomial in one variable
\[ \sum_{|\ell| \leq L} \hat{\alpha}_{L,-}(\ell) e(i \ell x) \]
where the \( \hat{\alpha}_{L,-}(\ell) \)s are defined as in [3, (2.2), lemma 5, (2.17)] with \( u = 1/2 + 1/\gamma \), \( v = 1 \).

Let us focus on the definition of \( B(x) \). Since we want \( B_L(x) = \sum_{1 \leq |i| \leq m} \beta_{L,i} \prod_{j \neq i} \alpha_{L,j} \left( x_i \right) \), in order to construct \( B_L(x) \) it is sufficient to define \( \beta_{L,i} \) for any \( 1 \leq |i| \leq m \):

(i) for \( 1 \leq i \leq m \), define
\[ \beta_{L,i}(x) = \frac{1}{2(L+1)} \left( \sum_{|\ell| \leq L} \left(1 - \frac{|\ell|}{L+1}\right) e(\ell x) + \sum_{|\ell| \leq L} \left(1 - \frac{|\ell|}{L+1}\right) e\left(\ell \left(x - \frac{1}{2} + \frac{1}{\gamma}\right)\right) \right) \]
\[ = \frac{1}{2(L+1)} \left( 2 + \sum_{1 \leq \ell \leq L} \left(1 - \frac{\ell}{L+1}\right) \left( \cos \left(\pi \ell - \frac{2\pi \ell}{\gamma}\right) \right. \right. \]
\[ + \sin \left( \pi \ell + \frac{2\pi \ell}{\gamma} \right) + 1 \right) \cos(2\pi \ell x) ; \]

(ii) for \( -m \leq i \leq 1 \), define
\[ \beta_{L,i}(x) = \frac{1}{2(L+1)} \left( \sum_{|\ell| \leq L} \left(1 - \frac{|\ell|}{L+1}\right) e\left(\ell \left(x - \frac{1}{2} - \frac{1}{\gamma}\right)\right) + \sum_{|\ell| \leq L} \left(1 - \frac{|\ell|}{L+1}\right) e(\ell(x - 1)) \right) \]
\[ = \frac{1}{2(L+1)} \left( 2 + \sum_{1 \leq \ell \leq L} \left(1 - \frac{\ell}{L+1}\right) \left( \cos \left(-\pi \ell - \frac{2\pi \ell}{\gamma}\right) \right. \right. \]
\[ + \sin \left(-\pi \ell - \frac{2\pi \ell}{\gamma}\right) + 1 \right) \cos(2\pi \ell x) . \]
Remember that the $n$th coefficients in the Chebyshev expansions of $\alpha_{L,i}$ and $\beta_{L,i}$ are given by

$$
\int_0^\pi \alpha_{L,i} \left( \frac{\theta}{\pi} \right) U_n(\theta) d\mu_{st} \text{ and } \int_0^\pi \beta_{L,i} \left( \frac{\theta}{\pi} \right) U_n(\theta) d\mu_{st}
$$

respectively; then part (iii) immediately follows, since the above integrals vanish when $n > 2L$. In [3, lemma 5] it is shown that $0 \leqslant \alpha_{L,i}(x) \leqslant 1$ for $x \in [0, 1]$. On the other hand, one has that $0 \leqslant |\beta_{L,i}(x)| \leqslant 1$ for any $i$ and for any $x \in [0, 1]$ by definition. Using the Cauchy-Schwarz inequality, we have

$$
\left| \int_0^\pi \alpha_{L,i} \left( \frac{\theta}{\pi} \right) U_n(\theta) d\mu_{st} \right|^2 \leqslant \int_0^\pi |\alpha_{L,i} \left( \frac{\theta}{\pi} \right)|^2 d\mu_{st} \cdot \int_0^\pi |U_n(\theta)|^2 d\mu_{st} \leqslant 1,
$$

and the same argument can be used for $\beta_{L,i}$, which proves part (ii). It remains to prove part (i). For any trigonometric polynomial $Y$, the constant term of its Chebyshev expansion is given by

$$
\int_0^\pi Y(\theta) d\mu_{st}.
$$

so we have that $\Delta$ in part (i) is given by

$$
\Delta = \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m - m \int_0^\pi \beta_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^{m-1} \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m - m \int_0^\pi \beta_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^{m-1}.
$$

Using the definition of $\beta_{L,\pm 1}$ we get

$$
\int_0^\pi \beta_{L,\pm 1} \left( \frac{\theta}{\pi} \right) d\mu_{st} = \frac{1}{L+1},
$$

so we can write $\Delta$ as

$$
\Delta = \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m - \frac{m}{L+1} \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^{m-1} \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m - \frac{m}{L+1} \left( \int_0^\pi \alpha_{L,1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^m \left( \int_0^\pi \alpha_{L,-1} \left( \frac{\theta}{\pi} \right) d\mu_{st} \right)^{m-1}.
$$

Notice that $\alpha_{L,\pm 1} \to \chi_{\pm \frac{1}{L}}$ in $L^2([0, 1]) L \to \infty$. Moreover, from [3, (2.6)] one has

$$
|\chi_{\pm \frac{1}{L}}(x) - \alpha_{L,\pm 1}(x)| \leqslant |\beta_{L,\pm 1}(x)|, \quad 0 \leqslant x \leqslant 1.
$$

From the Fourier expansion of $\beta_{L,\pm 1}(x)$,

$$
||\beta_{L,\pm 1}||_{L^2}^2 \leqslant \frac{8 + 3L}{(2L + 2)^2} \to 0.
$$
Thus,

\[
\int_0^\pi \alpha_{L,1^\pm} \left( \frac{\theta}{\pi} \right) d\mu_{st} \rightarrow \int_0^\pi \chi_{\pm \frac{1}{\sqrt{1+\gamma}}} \left( \frac{\theta}{\pi} \right) d\mu_{st} = \frac{1}{2} - \frac{1}{\gamma} + \frac{\sin\left( \frac{\pi}{\gamma} \right) \cos\left( \frac{\pi}{\gamma} \right)}{\pi}.
\]

This implies that there exists \( L_0 \), such that

\[
\int_0^\pi \alpha_{L,1^\pm} \left( \frac{\theta}{\pi} \right) d\mu_{st} \geq \frac{1}{2} - \frac{1}{\gamma}.
\]

Hence,

\[
\Delta \geq \left( \frac{1}{2} - \frac{1}{\gamma} \right)^{2m-2} \left( \left( \frac{1}{2} - \frac{1}{\gamma} \right)^2 - \frac{3m}{L+1} \right). \tag{2.13}
\]

If we assume further that \( L + 1 \geq 6m \left( \frac{1}{2} - \frac{1}{\gamma} \right)^{-2} \), we obtain

\[
\Delta \geq \frac{1}{2} \left( \frac{1}{2} - \frac{1}{\gamma} \right)^{2m} \tag{2.14}
\]

as desired.

### 3. Moments: proof of Theorem 1·8

#### 3-1. An auxiliary lemma

The following Lemma will be instrumental to the proof of Theorem 1·8.

**Lemma 3·1.** Assume the notation of Theorem 1·8, and let \( 0 \leq \alpha < \beta \leq 1 \). Then for every \( k \geq 2 \) there exist two constants \( C_1, C_2 \geq 1 \) depending only on \( c_8 \), such that

\[
\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^*} \left| \frac{1}{\sqrt{p}} \sum_{a_p < x \leq \beta p} t_{a,p}(x) \right|^{2k} \leq C_1^{2k} (\log k)^{2k} (\beta - \alpha)^{\frac{2k}{2k+1}} + C_2^{2k} p^{-\frac{1}{2}} (\log p)^{2k}.
\]

**Proof:** We start by applying Lemma 2·1 to obtain

\[
\frac{1}{\sqrt{p}} \sum_{a_p < x \leq \beta p} t_{a,p} = \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p/2} \hat{t}_{a,p}(n) \frac{1}{n} (1 - e((\beta - \alpha)n)e(\alpha n)) + (\beta - \alpha) \hat{t}_{a,p}(0) + O(1).
\]

To simplify the notation, define for any \(-p/2 \leq n \leq p/2\)

\[
c_n := \frac{(1 - e((\beta - \alpha)n))e(\alpha n)}{n},
\]

so we can write the above equation as

\[
\frac{1}{\sqrt{p}} \sum_{a_p < x \leq \beta p} t_{a,p}(x) = \frac{1}{2\pi i} \sum_{1 \leq |n| \leq p/2} \hat{t}_{a,p}(n) c_n + (\beta - \alpha) \hat{t}_{a,p}(0) + O(1).
\]
By the triangle inequality,
\[
\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^*} \left| \sum_{a p < x \leq \beta p} t_{a, p}(x) \right|^2 \leq \frac{1}{(p-1)\pi^{2k}} \sum_{a \in \mathbb{F}_p^*} \left| \sum_{1 < |n| < p/2} \hat{t}_{a, p}(n) a_n \right|^{2k} + O \left( 2^{4k} + 2^{4k} (\beta - \alpha)^2 c_{\delta}^{2k} \right)
\]
\[
= \frac{1}{(p-1)\pi^{2k}} \sum_{a \in \mathbb{F}_p^*} \left| \sum_{1 < |n| < p/2} \hat{t}_{1, p}(\tau_n \cdot a) a_n \right|^{2k} + O \left( 2^{4k} + 2^{4k} (\beta - \alpha)^2 c_{\delta}^{2k} \right),
\]
where in the first inequality we use the fact that \(\|\hat{t}_{a, p}\|_\infty \leq c(\mathcal{F}(\mathcal{F}_a, p)) \leq 10c(\mathcal{F}_a, p)^2 \leq 10c_2^2\) (see Remark 1 and [7, proposition 8.2]). Moreover, since we are assuming that \(G_{\text{geom}}^{\text{arith}} = G_{\text{arith}}^{\text{arith}} = \text{Sp}_{2g}(\mathbb{C})\), it follows that \(\hat{t}_{1, p}(\tau_y \cdot a) \in \text{Tr}(\text{USp}_{2g}(\mathbb{C})) = [-2g, 2g]\), i.e. \(\hat{t}_{a, p}\) is a real function for any \(p\) and \(a \in \mathbb{F}_p^*\). Let us bound the first term in the right-hand side of (3.1). Expanding the 2kth power we get
\[
\sum_{a \in \mathbb{F}_p^*} \sum_{n_1} \cdots \sum_{n_k} \sum_{l_1} \cdots \sum_{l_k} \prod_{i=1}^k \hat{t}_{1, p}(\tau_{n_i} \cdot a) \hat{t}_{1, p}(\tau_{l_i} \cdot a) a_n \bar{a}_{l_i}.
\]
Arguing as in Lemma 2.5, we obtain that
\[
\left| \sum_{a \in \mathbb{F}_p^*} \prod_{i=1}^k \hat{t}_{1, p}(\tau_{n_i} \cdot a) \hat{t}_{1, p}(\tau_{l_i} \cdot a) - m(\tau_{n,1}) p \right| \leq \delta_1^{2k} \sqrt{p},
\]
where the constant \(\delta_1\) depends only on \(c_{\delta}\), \(\tau_{n,1} := (\tau_{n_1}, \ldots, \tau_{n_k}, \tau_{l_1}, \ldots, \tau_{l_k})\), and
\[
m(\tau_{n,1}) = \prod_{\tau \in \tau_{n,1}} \text{multi}(\text{Std}^{\otimes m_{\tau}}),
\]
where \(m_{\tau}\) is the multiplicity of \(\tau\) in the tuple \(\tau_{n,1}\) and \(\text{Std}\) is the standard representation of \(\text{Sp}_{2g}(\mathbb{C})\) ([8, corollary 1.7]). Notice that \(m(\tau_{n,1}) \neq 0\) if and only if \(m_{\tau}\) is even for any \(\tau\) occurring in \(\tau_{n,1}\) ([8, corollary 1.6]). From this we get
\[
\sum_{a \in \mathbb{F}_p^*} \left| \sum_{1 < |n| < p/2} \hat{t}_{a, p}(n) a_n \right|^{2k} \leq A + B,
\]
where
\[
A = p \sum_{n,1} c_{n_1} \cdots c_{n_k} c_{l_1} \cdots c_{l_k} m(\tau_{n,1}),
\]
and
\[
B = \left| \sqrt{p} \delta_1^{2k} \sum_{n,1} c_{n_1} \cdots c_{n_k} c_{l_1} \cdots c_{l_k} \right|.
\]
Let us first bound \(B\):
\[
B \leq \sqrt{p} \delta_1^{2k} \sum_{n,1} |c_{n_1}| \cdots |c_{n_k}| |c_{l_1}| \cdots |c_{l_k}| = \sqrt{p} \delta_1^{2k} \left( \sum_{|c_n|} \right)^{2k}.
\]
On the size of the maximum of incomplete Kloosterman sums

On the other hand

\[ |c_n| \leq 2 \min \left( \frac{1}{n}, (\beta - \alpha)\pi \right) \leq \frac{2}{n}, \]

hence \( B \leq \sqrt{p} C_2^{2k} (\log p)^{2k} \) for some \( C_2 > 0 \) depending only on \( c_\delta \). To bound \( A \), we can proceed as follows: by definition, \( m(\tau_{n, 1}) \leq \gamma_1^{2k} \) for some \( \gamma_1 \) depending only on \( c_\delta \). Thus,

\[ A \leq \gamma_1^{2k} p \sum_{m} \sum_{(m_1, \ldots, m_{2k}) \in \nu(m)} c_{m_1} \cdots c_{m_{2k}}, \tag{3.2} \]

where \( \nu(m) := \{(m_1, \ldots, m_{2k}) : m_1 \cdots m_{2k} = m \text{ any } m_i \text{ appears an even number of times}\} \).

On the other hand, for any \( (m_1, \ldots, m_{2k}) \in \nu(m) \) we have that

\[ c_{m_1} \cdots c_{m_{2k}} \leq 2^{2k} \min \left( \frac{1}{m}, ((\beta - \alpha)\pi)^{2k} \right) =: c(m). \]

Let us focus our attention on the size of \( |\nu(m)| \). First observe that by definition, \( \nu(m) = 0 \) when \( m \) is not a square. Moreover, for any \( (m_1, \ldots, m_{2k}) \in \nu(m^2) \), we can find two sets \( S_1, S_2 \subset \{1, \ldots, 2k\} \) such that

\[ |S_1| = |S_2| = k, \quad S_1 \cap S_2 = \emptyset, \quad m = \prod_{i \in S_1} m_i = \prod_{j \in S_2} m_j. \]

Hence,

\[ |\nu(m^2)| \leq \binom{2k}{k} d_k(m)^2, \]

where \( d_k(m) := |\{(m_1, \ldots, m_k) : m_1 \cdots m_k = m\}| \). Inserting this into (3.2) we get

\[
A \leq \gamma_1^{2k} p \sum_{m} d_k(m)^2 c(m^2) \\
\leq \gamma_1^{2k} p \sum_{m \leq p} d_k(m)^2 c(m^2) + O_{k, \varepsilon}(p^\varepsilon). 
\]

It is shown in [2, lemma 4.1, pp. 437-438] that

\[
\sum_{m \leq p} d_k(m)^2 c(m^2) \leq 2^k (\log k)^{2k} \left( \frac{\pi}{\beta - \alpha} \right)^{-\frac{3}{2}} 
\]

which conclude the proof.

3.2. Proof of Theorem 1.8

We are finally ready to prove Theorem 1.8

Proof of Theorem 1.8. Let us start with the lower bound. By Lemma 2.2 for \( t = t_{a, p} \), \( N = k \) and \( \alpha = 1/2 \), we have that

\[
M(t_{a, p}) \geq \frac{1}{2\pi} \left| \sum_{1 \leq n \leq k \atop n = 1(2)} \hat{f}_{t_{a, p}}(\tau_n \cdot a) \right| + O_{c(\delta)}(1) \tag{3.3}
\]
for any \( p \) large enough and \( a \in \mathbb{F}_p^\times \). By definition of a 1-parameter family of \( \text{Sp}_{2g} \)-type, the sheaf \( \text{FT}(\mathcal{F}_{1,p}) \) is a bountiful sheaf of \( \text{Sp}_{2g} \)-type. This implies that the sheaves \( \text{FT}(\mathcal{F}_{1,p}), \tau_{1}^{*} \text{FT}(\mathcal{F}_{1,p}), \ldots, \tau_{k}^{*} \text{FT}(\mathcal{F}_{1,p}), \tau_{k}^{*} \text{FT}(\mathcal{F}_{1,p}) \) satisfy the Goursat–Kolchin–Ribet criterion (\([19\text{, chapter 1-8]}\)). Thus combining \([8\text{, lemma 2.4]}\) with Deligne’s equidistribution Theorem, we obtain that the sequence

\[
\{\hat{t}_{1,p}(\tau_{1} \cdot a), \hat{t}_{1,p}(\tau_{1} \cdot a), \ldots, \hat{t}_{1,p}(\tau_{k} \cdot a), \hat{t}_{1,p}(\tau_{k} \cdot a)\}_{a \in \mathbb{F}_p}
\]

become equidistributed in \((\prod_{i=1}^{2k}[-2g, 2g], \mu_{\text{USp}_{2g}}^{\otimes 2k})\) as \( p \to \infty \), where \( \mu_{\text{USp}_{2g}} \) is the pushforward of the Haar measure of \( \text{USp}_{2g}(\mathbb{C}) \subset \text{Sp}_{2g}(\mathbb{C}) \) (notice that \([-2g, 2g] = \text{Tr}(\text{USp}_{2g}(\mathbb{C}))) \). Now if we define

\[
S_{k,p} = \{a \in \mathbb{F}_p^\times : \hat{t}_{1,p}(\tau_{i} \cdot a) > \sqrt{2g} \forall 0 < i < k, \hat{t}_{1,p}(\tau_{i} \cdot a) < -\sqrt{2g} \forall 0 < i < k\},
\]

we get that

\[
M(t_{a,p}) \geq \left( \frac{g}{\sqrt{2\pi}} + o(1) \right) \log k
\]

for any \( a \in S_{k,p} \). Hence,

\[
\frac{1}{p - 1} \sum_{a \in \mathbb{F}_p^\times} M(t_{a,p})^{2k} \geq \frac{1}{p - 1} \sum_{a \in S_{k,p}} M(t_{a,p})^{2k} \geq \left( \frac{cg}{\sqrt{2\pi}} + o(1) \right)^{2k} (\log k)^{2k},
\]

where \( c = \mu_{\text{USp}_{2g}}([-2g, 2g]) \gg 1 \). Let us now prove the upper bound. For any \( a \in \mathbb{F}_p^\times \) let \( N_{a,p} \) be the smallest integer such that

\[
M(t_{a,p}) = \left| \frac{1}{\sqrt{p}} \sum_{x \in N_{a,p}} t_{a,p}(x) \right|.
\]

At this point we would like to apply Lemma 3.1 but the \( N_{a,p} \)'s might be very different from one another. To go around this issue, following the strategy of \([24\text{ and }2]\), we will use the Rademacher–Menchof trick: first of all expand \( N_{a,p} / p \) in base 2

\[
\frac{N_{a,p}}{p} = \sum_{j=1}^{\infty} a_j 2^{-j} \quad a_j \in \{0, 1\},
\]

and let \( N_{a,p}(L_{p}) / p \) be the truncation of this series at the summand of power \( L_{p} \). Then we have

\[
M(t_{a,p}) \leq \left| \frac{1}{\sqrt{p}} \sum_{x \leq N_{a,p}(L_{p})} t_{a,p}(x) \right| + E(a, p, L_{p}),
\]

where

\[
E(a, p, L_{p}) = \left| \frac{1}{\sqrt{p}} \sum_{N_{a,p}(L_{p}) < x \leq N_{a,p}} t_{a,p}(x) \right|.
\]
Notice that the number of summands in $E(a, p, L_p)$ is $\leq p/2L_p$. An application of the Hölder inequality leads to

$$M(t_{a, p})^{2k} \leq 2^k \left( \sum_{l \leq L_p} \frac{1}{l^{2\gamma}} \right)^{2k-1} \left( \sum_{l \leq L_p} l^{2k\gamma} \sum_{0 \leq m \leq 2^l-1} \frac{1}{\sqrt{p}} \sum_{N_{a, p}(l) < x \leq N_{a, p}(l+1)} t_{a, p}(x)^{2k} \right) + 2^k E(a, p, L_p)^{2k}.$$

Observe first that $N_{a, p}(l+1) \leq N_{a, p}(l) + p2^{-(l+1)}$. Moreover, there are $2^{l-1}$ possibilities for the value of $N_{a, p}(l)$, so

$$M(t_{a, p})^{2k} \leq 2^k \left( \sum_{l \leq L_p} \frac{1}{l^{2\gamma}} \right)^{2k-1} \left( \sum_{l \leq L_p} l^{2k\gamma} \sum_{0 \leq m \leq 2^l-1} \frac{1}{\sqrt{p}} \sum_{p \frac{m}{2^{l+1}} < x \leq p \frac{m}{2^l}} t_{a, p}(x)^{2k} \right) + 2^k E(a, p, L_p)^{2k}.$$

We can now apply Lemma 3.1 and choose $\gamma = 3/2$ to obtain

$$\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^*} M(t_{a, p})^{2k} \leq 2^k \left( \sum_{l \leq L_p} \frac{1}{l^{3\gamma}} \right)^{2k-1} \left( \sum_{l \leq L_p} l^{3k2l} \left( \gamma^{2k}(\log k)^{2k} 2^{-\frac{m}{\log p}} \right) + \delta^{2k} p^{-\frac{1}{2}} (\log p)^{2k} \right) + \frac{2^k}{p-1} \sum_{a \in \mathbb{F}_p^*} E(a, p, L_p)^{2k}.$$

Choosing $L_p := \log_2 \left( \frac{p^2}{\log p} \right)$, we get

$$(2\delta)^2 \left( \sum_{l \leq L_p} \frac{1}{l^{3\gamma}} \right)^{2k-1} \sum_{l \leq L_p} l^{3k2l} p^{-\frac{1}{2}} (\log p)^{2k} \ll_k (\log p)^{8k} 2^{L_p} p^{-\frac{1}{2}} 
\ll_k 1,$$

where in the first step we are using the fact that

$$\sum_{l} \frac{1}{l^{3\gamma}} \ll 1.$$

Moreover, using the following inequality from [2, theorem 1.1, p. 440]

$$\sum_{l \leq L_p} l^{3k2l} 2^{-\frac{m}{\log k}} \leq \exp(3k \log \log k + O(k)),$$

we get

$$(2\gamma)^{2k} (\log k)^{2k} \left( \sum_{l \leq L_p} \frac{1}{l^{3\gamma}} \right)^{2k-1} \sum_{l \leq L_p} l^{2k2l} 2^{-\frac{m}{\log k}} \ll_k 1.$$
On the other hand, since the length of $E(a, p, L_p)$ is at most $p/2^{L_p} = p^2(\log p)^{8k}$, an application of [9, theorem 1.1] leads to

$$|E(a, p, L_p)| \leq 4c_\delta \log (4e^8 (\log p)^{8k}) .$$

Then

$$\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^\times} E(a, p, L_p)^{2k} \leq (Ck)^k (\log p)^{2k},$$

and this completes the proof of the first part of the Theorem. Now let us assume that

$$\left| \sum_{N \leq x \leq N+H} t_{a, p}(x) \right| \ll_{c, \delta} H^{1-\varepsilon}$$

holds uniformly for any $1 < N < p, p^{1/2-\varepsilon/2} < H < p^{1/2+\varepsilon/2}$ and $a \in \mathbb{F}_p^\times$. Starting again from

$$\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^\times} M(t_{a, p})^{2k} \leq 2^{2k} \left( \sum_{l \leq L_p} \frac{1}{l^{2\gamma/3}} \right)^{2k-1} \left( \sum_{l \leq L_p} l^{2k\gamma} 2^l \right) + \delta^{2k} p^{-\frac{1}{2}} (\log p)^{2k},$$

we choose $L_p = (1 - \varepsilon/2) \log_2 p$, and obtain by (3.4) that there exists some $\varepsilon' > 0$ such that

$$E(a, p, L_p)^{2k} = \left| \frac{1}{\sqrt{p}} \sum_{a \in \mathbb{F}_p^\times} t_{a, p}(x) \right|^{2k} \ll_{c, \delta, \varepsilon} p^{-\varepsilon'}$$

for any $p$ and any $a \in \mathbb{F}_p^\times$. Hence,

$$\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^\times} E(a, p, L_p)^{2k} \ll_{c, \delta, \varepsilon} p^{-\varepsilon'}.$$

Moreover,

$$p^{-\frac{1}{2}} (\delta \log p)^{2k} \left( \sum_{l \leq L_p} l^{2k\gamma} 2^l \right) \leq p^{-\frac{1}{2}} (\delta \log p)^{2k} \left( \sum_{l \leq L_p} l^{4k} 2^l \right) \ll_{k, c, \delta} p^{-\frac{1}{2}} (\log p)^{2k} 2^{L_p} \ll p^{-\varepsilon/2} (\log p)^{2k} .$$

Putting it all together, we get

$$\frac{1}{p-1} \sum_{a \in \mathbb{F}_p^\times} M(t_{a, p})^{2k} \leq (2\gamma \log k)^{2k} \left( \sum_{l \leq L_p} \frac{1}{l^{2\gamma/3}} \right)^{2k-1} \left( \sum_{l \leq L_p} l^{2k\gamma} 2^l \right) \ll_{k, c, \delta} p^{-\varepsilon'/2} .$$
On the size of the maximum of incomplete Kloosterman sums

for some $\varepsilon'' > 0$. On the other hand, [2, theorem 1·1 p. 440] implies that

$$\sum_{l \leq L_p} \frac{1}{l^{2g}} \leq (\gamma - 1)^{1-2k}, \quad \sum_{l \leq L_p} l^{2k} 2^l 2^{-\frac{k}{\log k}} \leq \exp(2k\gamma \log \log k + O(k)).$$

Hence, by choosing $\gamma = 1 + 1/\log \log k$ we obtain the desired result.

We conclude with the proof of Corollary 1·9.

**Proof of Corollary 1·9.** For part (i), observe that it follows from the proof of the lower bound of Theorem 1·8 that any element $a$ in the set

$$S_{h, p} = \left\{ a \in \mathbb{F}_p^\times : \hat{t}_{1, p}(\tau_i \cdot a) > \sqrt{2}g \quad \forall 0 < i < h, \hat{t}_{1, p}(\tau_{-i} \cdot a) < -\sqrt{2}g \quad \forall 0 < i < h \right\}$$

satisfies that $M(t_a, p) > (r/(\sqrt{2}\pi) + o(1)) \log h$. Moreover we have that $|S_{h, p}| > c^{2h}$ for some absolute constant $0 < c < 1$. Choosing $h = \exp((g/(\sqrt{2}\pi) + o(1))^{-1} \cdot A)$ we get

$$D_{\delta}(A) \geq |S_{\exp((g/(\sqrt{2}\pi) + o(1))^{-1} \cdot A), p}|.$$ 

The proof of (ii) is exactly the same as in [2, theorem 1·3].

**Acknowledgements.** I am most thankful to my advisor, Emmanuel Kowalski, for suggesting this problem and for his guidance during these years. I also would like to thank Youness Lamzouri for informing me about his work on sum of incomplete Birch sums and Tal Horesh for her suggestions on a previous version of the paper. Finally, I am very grateful to the anonymous referee for their careful reading of the manuscript and their valuable comments.
