In-situ direct writing by electron and ion beam from solutions opens a pathway for resistless fabrication of nanostructures at high throughput. This method utilizes the electron beam (e-beam) or ion beam (i-beam) as an ionizing source that decomposes solvent (specifically water here) molecules to generate aqueous electrons and other radicals in a complex cascade of reaction pathways [1]. In water, radiolytically generated aqueous electrons (e_{aq}^-) act as a reducing agent when interacting with organic and inorganic compounds, this may be harnessed to guide local deposition of the material directly from the precursor. Since electron and ion beam microscopes generally operate in high vacuum, (except variable pressure scanning electron microscope) it is necessary to utilize cells to encapsulate the liquid precursor in order to prevent evaporation. These liquid cells are composed of silicon microchips and silicon nitride membranes. *In-situ* liquid cell electron microscopy, has been used to investigate the mechanisms of electron beam induced nucleation, growth, and coalescence of nanoparticles in a variety of precursors at various concentrations [2-5]. To date, most *in-situ* liquid cell studies have been performed using a scanning electron microscope (SEM) or a (scanning) transmission electron microscope (S)TEM [1-2].

Use of the helium beam with the opposite charge and shorter mean free path offers the potential for the localization of the reaction zone on the single digit nanometer scale. Here, we will present our results demonstrating writing of platinum structures from liquid in a platinum chloride solution using helium ions with sub-10 nm resolution (Figure 1). Using data analytics on acquired in-situ growth movies (Figure 2) we are able to elucidate the main statistical descriptors for helium ion beam initiated platinum structure growth. The possible mechanisms of beam induced growth and ultrahigh localization of reaction zone are discussed. Furthermore, we will discuss optimization of solution chemistry and instrumental parameters as they relate to the quality and thickness of structures and the extension to device fabrication on a single digit nanometer level.
