# ON THE ORDER OF THE SYLOW SUBGROUPS OF THE AUTOMORPHISM GROUP OF A FINITE GROUP 

by K. H. HYDE

(Received 30 September, 1968; revised 26 September, 1969)

1. Introduction. Given any finite group $G$, we wish to determine a relationship between the highest power of a prime $p$ dividing the order of $G$, denoted by $|G|_{p}$, and $|A(G)|_{p}$, where $A(G)$ is the automorphism group of $G$. It was shown by Herstein and Adney $[8]$ that $|A(G)|_{p} \geqq p$ whenever $|G|_{p} \geqq p^{2}$. Later Scott [16] showed that $|A(G)|_{p} \geqq p^{2}$ whenever $|G|_{p} \geqq p^{3}$. For the special case where $G$ is abelian, Hilton [9] proved that $|A(G)|_{p} \geqq p^{n-1}$ whenever $|G|_{p} \geqq p^{n}$. Adney [1] showed that this result holds if a Sylow $p$-subgroup of $G$ is abelian, and gave an example where $|G|_{p}=p^{4}$ and $|A(G)|_{p}=p^{2}$. We are able to show in Theorem 4.5 that, if $|G|_{p} \geqq p^{5}$, then $|A(G)|_{p} \geqq p^{3}$.

In the general case, Ledermann and Neumann [11] showed that there exists a function $g(h)$ having the property that $|A(G)|_{p} \geqq p^{h}$ whenever $|G|_{p} \geqq p^{g(h)}$, and gave an upper bound for $g(h)$. Later, Green [6] improved their result by showing that

$$
g(h) \leqq \frac{1}{2}\left(h^{2}+3 h+2\right) .
$$

Howarth [10] then proved that, for $h \geqq 12, \dagger$

$$
g(h) \leqq\left\{\begin{array}{llll}
\frac{1}{2}\left(h^{2}+3\right) & \text { for } & h & \text { odd } \\
\frac{1}{2}\left(h^{2}+4\right) & \text { for } & h & \text { even } .
\end{array}\right.
$$

We are able to improve this result by showing that, for all $h$,

$$
g(h) \leqq \frac{1}{2}\left(h^{2}-h+6\right) .
$$

We shall also consider the special case where $G$ is a p-group, and show that in this case $|A(G)|_{p} \geqq p^{h}$ whenever $|G| \geqq p^{A}$, where

$$
A= \begin{cases}\frac{1}{2}\left(h^{2}-3 h+6\right) & \text { for } h \geqq 5, \\ h+1 & \text { for } h \leqq 4\end{cases}
$$

We point out that all groups considered in this paper are finite. Also, the letter $p$ will always stand for a prime.
2. Central automorphisms. An automorphism $\sigma$ such that $g^{-1} g^{\sigma}$ is in the center of $G$, for all $g$ in $G$, is called central. The set of all central automorphisms of $G$ forms a subgroup of $A(G)$, which we denote by $A_{c}(G)$. It is easy to show that $A_{c}(G)$ is the centralizer of the inner automorphism group $I(G)$ in $A(G)$. From this it follows that $A_{c}(G)$ is normal in $A(G)$, and that
$\dagger$ Howarth remarks that the result can be shown to be valid for $h \geqq 6$.
$A_{c}(G)$ contains $I(G)$ if and only if $I(G)$ is abelian. If $G^{\prime}$ is the derived group of $G$, then $G^{\prime}$ is left fixed elementwise by any $\sigma$ in $A_{c}(G)$, and $\sigma$ induces the identity on $G / Z$.

The mapping $f_{\sigma}$ defined by $g f_{\sigma}=g^{-1} g^{\sigma}$ is a homomorphism of $G$ into $Z$. The map $\sigma \rightarrow f_{\sigma}$ is a one-one map of $A_{c}(G)$ into the group $\operatorname{Hom}(G, Z)$ of homomorphisms of $G$ into $Z$. On the other hand, if $f$ is in $\operatorname{Hom}(G, Z)$, then $\sigma: g \rightarrow g(g f)$ defines an endomorphism of $G$. It has been shown by Adney and Yen [2] that, if $G$ has no abelian direct factor, then the endomorphism $\sigma: g \rightarrow g(g f)$ is an automorphism of $G$. If $G$ is a group which does not have an abelian direct factor, we say that $G$ is purely non-abelian. We shall for brevity call such a group a $P N$-group.

We note that, for any $f$ in $\operatorname{Hom}(G, Z)$, the kernel of $f$ contains $G^{\prime}$ so that $\operatorname{Hom}(G, Z)=$ Hom $\left(G / G^{\prime}, Z\right)$. We now state the result of Adney and Yen as a lemma for future reference.

Lemma 2.1. If $G$ is a $P N$-group, then the order of $\operatorname{Hom}\left(G / G^{\prime}, Z\right)$ is equal to the order of $A_{c}(G)$.

For a prime $p$ we shall denote the cyclic group of order $p^{a}$ by $C\left(p^{a}\right)$. We shall denote the minimum of two real numbers $x$ and $y$ by $\min (x, y)$. The proofs of the following two lemmas are straightforward.

Lemma 2.2. If $H=C\left(p^{a}\right) \times C\left(p^{b+x}\right), K=C\left(p^{d}\right)$ and $H_{1}=C\left(p^{a+x}\right) \times C\left(p^{b}\right)$, where $a \geqq b$, then $\left|\operatorname{Hom}\left(H_{1}, K\right)\right| \leqq|\operatorname{Hom}(H, K)|$. We also have $\left|\operatorname{Hom}\left(K, H_{1}\right)\right| \leqq|\operatorname{Hom}(K, H)|$.

Lemma 2.3. If $H$ and $K$ are abelian p-groups, then $|\operatorname{Hom}(H, K)| \geqq \min (|H|,|K|)$.
The following result will reduce our problem to the case of a $p$-group.
Lemma 2.4. If $\left|A_{c}(G)\right|_{p}=|A(G)|_{p}$, then $G=G_{p} \times G_{p^{\prime}}$, where $G_{p}$ is a Sylow $p$-subgroup of $G$.

Proof. Let $x$ be an element of a Sylow $p$-subgroup $G_{p}$. If $T_{x}$ is the inner automorphism induced by $x$, then $o\left(T_{x}\right)=p^{a}$ for some $a$. Let $A_{p}$ be a Sylow $p$-subgroup of $A(G)$ which contains $T_{x}$. Since $\left|A_{c}(G)\right|_{p}=|A(G)|_{p}$ and since $A_{c}(G)$ is normal in $A(G)$, by Sylow's Theorem, $A_{p} \subseteq A_{c}(G)$. Therefore $T_{x}$ is central and, for any $g \in G,(g Z) T_{x}=g^{x} Z=g Z$. Hence $[g, x] \in Z$ for all $x \in G_{p}$, and so $\left[G, G_{p}\right]$ is contained in the center of $G$. Now let $H$ be any subgroup of $G_{p}$ and $x$ an element of order prime to $p$ which normalizes $H$. For any $h$ in $H$ we have $h T_{x}=$ $h[h, x]$ and $[h, x]$ is in $H \cap\left[G, G_{p}\right] \subseteq H \cap Z(G)$. Let $n=o\left(T_{x}\right)$; then $h T_{x}^{n}=h[h, x]^{n}=h$. But $n$ divides the order of $x$, which is prime to $p$, and $[h, x]$ is in $G_{p}$. Therefore $[h, x]=e$ and $x$ centralizes $H$. From Theorem 14.4.7 of Hall [7], $G_{p}$ has a normal complement $G_{p^{\prime}}$. Since [ $G_{p}, G$ ] is contained in the center, $G_{p} Z$ is normal in $G$. Also $G_{p}$ is characteristic in $G_{p} Z$ and therefore normal in $G$. We now have that $G=G_{p} \times G_{p^{\prime}}$.
3. Automorphisms of p-groups. We shall make use of the following results. The first is due to Gaschütz [5].

Lemma 3.1. If $G$ is a non-abelian p-group, then there exists an outer automorphism of $G$ which has order a power of $p$.

The proof of the following result is given in a paper by Otto [12].
Lemma 3.2. If the p-group $G$ is a direct product of an abelian group $H$ and a PN-group $K$, then
(i) $|A(G)|_{p} \geqq|H||A(K)|_{p}$ and
(ii) $\left|A_{c}(G)\right|_{p} \geqq|H|\left|A_{c}(K)\right|_{p}$.

The next lemma is due to Wiegold [17].
Lemma 3.3. Let $p$ be a prime and $G$ a group with $|G| Z \mid=p^{r}$. Then $G^{\prime}$ is a p-group of order at most $p^{r(r-1) / 2}$.

It is known that, if $|G / Z|_{p}=p^{r}$, then $\left|G^{\prime} \cap Z\right|_{p} \leqq p^{p(r-1) / 2}$.
This result can be found in a paper of Howarth [10, Lemmas 4.2 to 4.5].
From this we get the following result.
Lemma 3.4. If $G$ is a group with $|G / Z|_{p}=p^{r}$, then $\left|G^{\prime}\right|_{p} \leqq p^{r(r+1) / 2}$.
Theorem 3.5. If $G$ is a p-group of order at least $p^{h+1}$ and $h \leqq 4$, then $|A(G)|_{p} \geqq p^{h}$.
Proof. The result holds for abelian groups, so we shall assume that $G$ is non-abelian. Hence $|I(G)|=|G / Z| \geqq p^{2}$. Since there also exists an outer automorphism of $p$-power order, we have $|A(G)|_{p} \geqq p^{3}$. This leaves only the case where $h=4$. In this case, if $|G / Z| \geqq p^{3}$, then, as in the preceding argument, $|A(G)|_{p} \geqq p^{4}$. It will now be sufficient to consider the case where $|G| \geqq p^{5}$ and $|G / Z|=p^{2}$. From Lemma 3.3, $\left|G^{\prime}\right|=p$ and $\left|G / G^{\prime}\right| \geqq p^{4}$. Now $G / Z$ is elementary abelian and is isomorphic to a subgroup of $G / G^{\prime}$. Therefore $G / G^{\prime}$ has at least two cyclic factors. We have $|Z| \geqq p^{3}$ and so, by Lemma 2.2, $\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right| \geqq$ $|\operatorname{Hom}(H, K)|$, where $H \cong C\left(\rho^{3}\right) \times C(p)$ and $K \cong C\left(p^{3}\right)$. If $G$ is purely non-abelian, then, from Lemma 2.1,

$$
\left|A_{c}(G)\right|=\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right| \geqq|\operatorname{Hom}(H, K)|=p^{4}
$$

If $G$ has an abelian direct factor, we write $G=H \times K$ with $H$ abelian and $K$ a $P N$-group and apply the previous results to get

$$
|A(G)|_{p} \geqq|H||A(K)|_{p} \geqq|H||K| / p=|G| / p \geqq p^{4}
$$

Theorem 3.6. If $G$ is a p-group of order at least $p^{g(h)}$ with $g(h)=\frac{1}{2}\left(h^{2}-3 h+6\right)$ and $h \geqq 5$, then $|A(G)|_{p} \geqq p^{h}$.

Proof. The result holds if $G$ is abelian. We therefore consider the case where $G$ is nonabelian. If $|G / Z| \geqq p^{h-1}$, then $|I(G)| \geqq p^{h-1}$. By Lemma 3.1 there exists an outer automorphism $\alpha$ which has order a power of $p$, and $\alpha$ along with $I(G)$ will generate a subgroup whose order is divisible by $p^{h}$.

We now consider the case where $|G / Z| \leqq p^{h-2}$, and $G$ is purely non-abelian. From Lemma 3.3,

$$
\left|G^{\prime}\right| \leqq p^{\left(h^{2}-5 h+6\right) / 2}
$$

and so $\left|G / G^{\prime}\right| \geqq p^{h}$. Also

$$
|Z| \geqq p^{\left(h^{2}-5 h+10\right) / 2}
$$

and, for $h \geqq 5, \frac{1}{2}\left(h^{2}-5 h+10\right) \geqq h$. We apply Lemma 2.1 and Lemma 2.3 to get

$$
\left|A_{c}(G)\right|=\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right| \geqq p^{h}
$$

If $|G / Z| \leqq p^{h-2}$ and $G$ has an abelian direct factor, then we write $G=H \times K$, where $H$ is abelian and $K$ is a $P N$-group. From Lemma 3.2,

$$
|A(G)|_{p} \geqq|H||A(K)|_{p} .
$$

Let $|H|=p^{r}$ so that $|K| \geqq p^{g(h)-r}$. If $r \geqq h$, we have the result. We therefore take $h \geqq r$, and show that $|A(K)|_{p} \geqq p^{h-r}$. If $h-r \geqq 5$, then $2 r h \geqq r^{2}+5 r$, which implies that $g(h)-r \geqq$ $g(h-r)$. From the first part of the proof for $P N$-groups, we have $|A(K)|_{p} \geqq p^{h-r}$. In the case in which $h-r \leqq 4$, we have $h^{2}-5 h+4 \geqq 0$ for $h \geqq 5$, which implies that $g(h)-r \geqq h-r+1$. From Theorem 3.5, we get $|A(K)|_{p} \geqq p^{h-r}$. This completes the proof.
4. The main results. We shall now find a bound for the least function $g(h)$ such that $|A(G)|_{p} \geqq p^{h}$ whenever $|G|_{p} \geqq p^{g(h)}$. It was conjectured that $g(h)=h+1$, but it was pointed out by Adney [1] that this is not true. Let $G$ be the general linear group $G L(2,19)$. The order of $G$ is $\left(19^{2}-1\right)\left(19^{2}-19\right)$, and so $|G|_{3}=3^{4}$. The order of the automorphism group of $G$ is $2|I(G)|$ and so

$$
|A(G)|_{3}=|G / Z|_{3}=3^{2}
$$

This example can be extended to show that $g(h) \geqq 2 h-1 . \dagger$ It is known that, if $a$ and $d$ are integers which are relatively prime, then the set $\{a+n d \mid n=0,1,2, \ldots\}$ contains an infinite number of primes. Let $a=1+p^{n}$ and $d=p^{n+1}$; then $a$ and $d$ are relatively prime and, for some $k, 1+p^{n}+k p^{n+1}$ ( $=q$ say) is a prime. Now let $G=G L(2, q)$; then the order of $G$ is $(q+1) q(q-1)^{2}$. For an odd prime $p, p^{n}$ divides $q-1, p^{n+1}$ does not divide $q-1$, and $p$ does not divide $q$ or $q+1$. Hence the highest power of $p$ dividing the order of $G$ is $p^{2 n}$. Now $|Z(G)|=q-1$ and so $|I(G)|=(q+1) q(q-1)$. Since $q$ is a prime, $|A(G)|=2|I(G)|$, and the highest power of $p$ dividing $|A(G)|$ is $p^{n}$. Therefore in seeking a bound for the least function $g(h)$ such that $p^{h} \leqq|A(G)|_{p}$ whenever $|G|_{p} \geqq p^{g(h)}$, we must have $g(h) \geqq 2 h-1$, where $h \geqq 2$. We have thus proved the following theorem.

Theorem 4.1. For $h \geqq 2$, the least function $g(h)$ such that $|A(G)|_{p} \geqq p^{h}$ whenever $|G|_{p} \geqq$ $p^{g(h)}$, satisfies the inequality $g(h) \geqq 2 h-1$.

Our main problem in this section will be to find an upper bound for $g(h)$, and we shall show that $g(h) \leqq \frac{1}{2}\left(h^{2}-h+6\right)$. We shall be mainly concerned with central automorphisms, and shall repeatedly use the fact that, for $P N$-groups, $\left|A_{c}(G)\right|=\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|$. We are interested in finding the highest order of a prime $p$ which divides $\left|A_{c}(G)\right|_{p}$. We note that $\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p}=\left|\operatorname{Hom}\left(\left(G / G^{\prime}\right)_{p}, Z_{p}\right)\right|$, so that we can apply the lemmas in Section 2 as they apply to $p$-groups.
$\dagger$ The author is indebted to W. R. Scott for the proof of this result.

Lemma 4.2. If $G=H \times K$, where $H$ is abelian with order divisible by $p$ and $K$ is a group with $\left|Z(K) \cap K^{\prime}\right|$ divisible by $p$, then $|A(G)|_{p}>|A(K)|_{p}$.

Proof. If $|H|_{p}>p$, then $|A(H)|_{p} \geqq p$ and we have $|A(G)|_{p} \geqq|A(H)|_{p}>|A(K)|_{p}$. If $|H|_{p}=p$, it will be sufficient to consider the case in which $H \cong C(p)$. Since $A_{c}(G)$ is normal in $A(G)$, we have

$$
\begin{aligned}
|A(G)|_{p} & \geqq\left|A_{c}(G) A(K)\right|_{p} \\
& =\frac{\left|A_{c}(G)\right|_{p}|A(K)|_{p}}{\left|A_{c}(G) \cap A(K)\right|_{p}} \\
& =\frac{\left|A_{c}(G)\right|_{p}}{\left|A_{c}(K)\right|_{p}}|A(K)|_{p} .
\end{aligned}
$$

Therefore it will be sufficient to show that $\left|A_{c}(G)\right|_{p}>\left|A_{c}(K)\right|_{p}$. We shall now construct a central automorphism of order $p$ which is not induced by a central automorphism of $K$. First, we define a homomorphism of $G / G^{\prime}$ into $Z(G)$. We note that $G / G^{\prime} \cong H \times K / K^{\prime}$, and let $h$ be a generator of $H$. Since $p$ divides $\left|Z(K) \cap K^{\prime}\right|$, we can pick an element $z$ in $Z(K) \cap K^{\prime}$ of order $p$. The mapping defined by

$$
\begin{aligned}
& h \rightarrow z, \\
& k \rightarrow e, \text { for all } \bar{k} \text { in } K / K^{\prime}
\end{aligned}
$$

defines a homomorphism $f$ of $G / G^{\prime}$ into $Z$. As described in Section 2, there exists a corresponding central endomorphism $\sigma$ of $G$ defined by $g \sigma=g\left(g G^{\prime} f\right)$. Each $g$ in $G$ can be written in the form $g=\left(h^{n}, k\right)$, where $k$ is in $K$, and so $g \sigma=\left(h^{n}, k z^{n}\right)$ with $k z^{n}$ in $K$. We claim that $\sigma$ is an automorphism. Since $G$ is finite, it will be sufficient to show that $\operatorname{ker}(\sigma)=0$. Suppose there exists $\left(h^{n}, k\right) \neq e$ such that $\left(h^{n}, k\right) \sigma=\left(h^{n}, k z^{n}\right)=e$. Then $h^{n}=e$ and $n \equiv 0(\bmod p)$. Since $z$ is of order $p, z^{n}=e$ and $\left(h^{n}, k\right)=\left(h^{n}, k z^{n}\right)=e$, a contradiction. It is clear that the central automorphism $\sigma$ is of order $p$. Also $h \sigma=h z$, so that $\sigma$ is not an automorphism induced by an automorphism of $K$.

We shall now show that $\sigma$ centralizes $A_{c}(K)$. Let $\alpha$ be any element of $A_{c}(K)$; then

$$
\begin{aligned}
\left(h^{n}, k\right) \sigma^{-1} \alpha \sigma & =\left(h^{n}, k z^{-n}\right) \alpha \sigma=\left(h^{n},(k \alpha)\left(z^{-n} \alpha\right)\right) \sigma \\
& =\left(h^{n},(k \alpha)\left(z^{-n} \alpha\right) z^{n}\right) .
\end{aligned}
$$

Since $z^{-n}$ is in $K^{\prime}$ and $\alpha$ is central, we have $z^{-n} \alpha=z^{-n}$. Therefore $\left(h^{n}, k\right) \alpha^{\sigma}=\left(h^{n}, k\right) \alpha$ and $\sigma$ centralizes $A_{c}(K)$. We can form the subgroup $A_{c}(K)\langle\sigma\rangle$ and we have

$$
\left.\left|A_{c}(G)\right|_{p} \geqq\left|A_{c}(K)\langle\sigma\rangle\right|_{p}\right\rangle\left|A_{c}(K)\right|_{p}
$$

which is what we wanted to show.
Lemma 4.3. If $G$ is a $P N$-group such that $|G|_{p} \geqq p^{\left(h^{2}-h+2\right) / 2}$, where $h \geqq 3$ and $\left|G^{\prime} \cap Z\right|_{p}=1$, then $|A(G)|_{p} \geqq p^{h}$.

Proof. If $|G / Z|_{p} \geqq p^{h}$, the results holds. If $|G / Z|_{p} \leqq p^{h-2}$, then, by Lemma 3.4,
and $\left|G / G^{\prime}\right|_{p} \geqq p^{h}$. Also

$$
\left|G^{\prime}\right|_{p} \leqq p^{(h-2)(h-1) / 2}=p^{\left(h^{2}-3 h+2\right) / 2}
$$

$$
|Z|_{p} \geqq p^{\left(h^{2}-h+2\right) / 2-(h-2)}=p^{\left(h^{2}-3 h+6\right) / 2} \geqq p^{h}
$$

for integral values of $h$. Therefore

$$
\left|A_{c}(G)\right|_{p} \geqq \min \left(\left|G / G^{\prime}\right|_{p},|Z|_{p}\right) \geqq p^{h} .
$$

Finally, if $|G / Z|_{p}=p^{h-1}$, then, using the fact that $\left|G^{\prime} \cap Z\right|_{p}=1$, we obtain

Therefore

$$
\left|G^{\prime}\right|_{p}=\left|G^{\prime} / G^{\prime} \cap Z\right|_{p} \leqq\left.\left|G G^{\prime}\right| Z\right|_{p}=|G / Z|_{p}=p^{h-1}
$$

$$
\left|G / G^{\prime}\right|_{p} \geqq p^{\left(h^{2}-h+2\right) / 2-(h-1)}=p^{\left(h^{2}-3 h+4\right) / 2} \geqq p^{h-1}
$$

for integral values of $h$. Since $|G / Z|_{p}=p^{h-1}$, a similar argument shows that $|Z|_{p} \geqq p^{h-1}$, and we have

$$
\left|A_{c}(G)\right|_{p} \geqq \min \left(|Z|_{p},\left|G / G^{\prime}\right|_{p}\right) \geqq p^{h-1}
$$

If $|A(G)|_{p}>\left|A_{c}(G)\right|_{p}$, we have the desired result. If $|A(G)|_{p}=\left|A_{c}(G)\right|_{p}$, we apply Lemma 2.4 and obtain $G=G_{p} \times G_{p}$. If $G_{p}$ is abelian, then the result follows, since $\frac{1}{2}\left(h^{2}-h\right) \geqq h$ for $h \geqq 3$. If $G_{p}$ is non-abelian, then, by Lemma 3.1, there exists an outer automorphism of order a power of $p$ which together with $I(G)$ generates a group with order divisible by $p^{h}$.

Lemma 4.4. Let $H$ and $K$ be abelian p-groups with $|H|=p^{a}, \exp (H) \leqq p^{b},|K|=p^{t}$, and $t \leqq b$. Then $|\operatorname{Hom}(H, K)| \geqq p^{B}$, where $B=a t / b$.

Proof. Let $a=b q+r$, where $0 \leqq r<b$, let $H_{1}$ be a $p$-group of type ( $p^{b(1)}, \ldots, p^{b(q)}, p^{r}$ ) with $b(1)=\ldots=b(q)=b$, and let $K_{1}$ be cyclic of order $p^{t}$. Repeated application of Lemma 2.2 gives $\left|\operatorname{Hom}\left(H_{1}, K_{1}\right)\right| \leqq|\operatorname{Hom}(H, K)|$ but $\left|\operatorname{Hom}\left(H_{1}, K_{1}\right)\right|=p^{A}$, where $A=q t+\min (t, r)$. Now

$$
a t / b=(b q+r) t / b=q t+(r t) / b
$$

but neither $r$ nor $t$ exceeds $b$, so that $r t / b \leqq \min (t, r)$ and $A \geqq a t / b$, which proves the result.
We are now prepared to prove our main result. We shall show that the least function $g(h)$, such that $|A(G)|_{p} \geqq p^{h}$ whenever $|G|_{p} \geqq p^{g(h)}$, satisfies the inequality $g(h) \leqq \frac{1}{2}\left(h^{2}-h+6\right)$. We know from previous results ([8] and [16]) that $g(1)=2$ and $g(2)=3$. We begin by showing that $g(3)=5$. From Theorem 4.1, we know that $g(3) \geqq 5$. We must show that, if $|G|_{p} \geqq p^{5}$, then $|A(G)|_{p} \geqq p^{3}$. It will be sufficient to consider the case in which $|G / Z|_{p} \leqq p^{2}$. By Lemma 3.4, $\left|G^{\prime}\right|_{p} \leqq p^{3}$ and so $\left|G / G^{\prime}\right| \geqq p^{2}$. If $G$ is purely non-abelian, then

$$
\left|A_{c}(G)\right|_{p}=\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p} \geqq \min \left(\left|G / G^{\prime}\right|_{p},|Z|_{p}\right) \geqq p^{2}
$$

If the strict inequality holds, then we are done. Otherwise, we can apply Lemma 2.4 and write $G=G_{p} \times G_{p^{\prime}}$, where $G_{p}$ is a Sylow $p$-subgroup of $G$. This reduces the problem to the case of a p-group and, by Theorem 3.5, the result holds. If $G$ is not $P N$, then we write $G=H \times K$, where $H$ is abelian and $K$ is $P N$. We now look at the different possibilities for
$|H|_{p}$. The result follows immediately in each case except when $|H|_{p}=p$ and $|K|_{p}=p^{4}$. If $\left|K^{\prime} \cap Z(K)\right|$ is divisible by $p$, then, by Lemma 4.2, we obtain

$$
|A(G)|_{p}>|A(K)|_{p} \geqq p^{2}
$$

If $\left|K^{\prime} \cap Z(K)\right|_{p}=1$, then, applying Lemma 4.3, we have $|A(K)|_{p} \geqq p^{3}$. We now have the desired result, which is significant since it is best possible, and we state it as a theorem.

Theorem 4.5. If $|G|_{p} \geqq p^{5}$, then $|A(G)|_{p} \geqq p^{3}$.
We note that this is in agreement with our general result, since $5=g(3) \leqq \frac{1}{2}\left(3^{2}-3+6\right)$.
We now proceed to the general case. We shall need the following result, due to Howarth [10, Corollary 4.7, p. 168].

$$
\begin{equation*}
\exp (Z) \text { divides }|G / Z| \exp \left(G / G^{\prime}\right) \tag{4.6}
\end{equation*}
$$

We want to show that $|A(G)|_{p} \geqq p^{h}$ whenever

$$
|G|_{p} \geqq p^{\left(h^{2}-h+6\right) / 2}
$$

It is sufficient to consider the case in which $|G / Z|_{p} \leqq p^{h-1}$. In this case, $|Z|_{p} \geqq p^{\left(h^{2}-3 h+8\right) / 2}$, and, by Lemma 3.4, $\left|G^{\prime}\right|_{p} \leqq p^{\left(h^{2}-h\right) / 2}$, which implies that $\left|G / G^{\prime}\right|_{p} \geqq p^{3}$. Let $\left|G / G^{\prime}\right|_{p}=p^{t} \geqq p^{3}$; then, by (4.6),

$$
\begin{aligned}
\exp (Z)_{p} & \leqq|G / Z|_{p} \exp \left(G / G^{\prime}\right)_{p} \\
& \leqq p^{h-1}\left|G / G^{\prime}\right|_{p}=p^{h-1+t}
\end{aligned}
$$

Suppose now that $G$ is purely non-abelian. If $t \geqq h$, then, since $|Z|_{p} \geqq p^{h}$, we have

$$
\left|A_{c}(G)\right|_{p}=\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p} \geqq p^{h} .
$$

Therefore we consider the case in which $t \leqq h-1$. In this case we can apply Lemma 4.4 and get $\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p} \geqq p^{B}$ with

$$
B \geqq \frac{1}{2}\left(h^{2}-3 h+8\right) t /(h-1+t) \quad(=C \text { say }) .
$$

We can now show that $C \geqq h-1$. This is equivalent to showing that

$$
(t-2) h^{2}+(4-5 t) h+10 t-2 \geqq 0
$$

The discriminant of the quadratic in $h$ is $-15 t^{2}+48 t$, which is negative for $t \geqq 4$. Hence, for $t \geqq 4$, the above inequality holds. For $t=3$, we have $h^{2}-11 h+28 \geqq 0$, which holds for $h>6$ and $h=4$. We must now examine separately the cases in which $5 \leqq h \leqq 6$ and $\left|G / G^{\prime}\right|_{p}=p^{3}$. We wish to show that $\left|A_{c}(G)\right|_{p} \geqq p^{h-1}$. For $h=5,|Z|_{p} \geqq p^{9}$ and, by (4.6),

$$
\exp (Z)_{p} \leqq p^{4} p^{3}=p^{7}
$$

By Lemma 2.2,

$$
\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p} \geqq\left|\operatorname{Hom}\left(C\left(p^{7}\right) \times C\left(p^{2}\right), C\left(p^{3}\right)\right)\right| \geqq p^{4}
$$

For $h=6,|Z|_{p} \geqq p^{13}$ and, by (4.6), $\exp (Z)_{p} \leqq p^{5} p^{3}=p^{8}$. By Lemma 2.2,

$$
\left|\operatorname{Hom}\left(G / G^{\prime}, Z\right)\right|_{p} \geqq\left|\operatorname{Hom}\left(C\left(p^{8}\right) \times C\left(p^{5}\right), C\left(p^{3}\right)\right)\right| \geqq p^{5}
$$

We now have $\left|A_{c}(G)\right|_{p} \geqq p^{h-1}$. If $|A(G)|_{p}>\left|A_{c}(G)\right|_{p}$, the desired result follows. Otherwise, we may apply Lemma 2.4 , so that $G=G_{p} \times G_{p^{\prime}}$. Since $|A(G)|_{p} \geqq\left|A\left(G_{p}\right)\right|_{p}$, we can apply Theorem 3.5 and Theorem 3.6, obtaining $|A(G)|_{p} \geqq p^{h}$, since $\frac{1}{2}\left(h^{2}-h+6\right)$ is greater than both $\frac{1}{2}\left(h^{2}-3 h+6\right)$ and $h+1$.

Now suppose $G$ has an abelian direct factor, and write $G=H \times K$, where $H$ is abelian and $K$ is purely non-abelian. Let $|H|_{p}=p^{r}$ and

$$
|K|_{p} \geqq p^{\left(h^{2}-h+6\right) / 2-r}
$$

If $r=0$, then the problem reduces to the case previously considered. Also, if $r \geqq h+1$, then $|A(H)|_{p} \geqq p^{h}$, which gives the desired result. For $1 \leqq r \leqq h$, we shall consider two cases, $2 \leqq r \leqq h$ and $1=r \leqq h$. Since the theorem is known to hold for $h \leqq 3$, we shall assume that $h>3$. We know that $|A(H)|_{p} \geqq p^{r-1}$, and so we shall show that $|A(K)|_{p} \geqq p^{h-r+1}$. For $r>2$ and $h \geqq r$, we can show that

$$
2 h r \geqq r^{2}+2 h+r
$$

For $r=2$ this inequality reduces to $h \geqq 3$. Therefore, for $2 \leqq r \leqq h$, the inequality holds, and from it we get

$$
\frac{1}{2}\left(h^{2}-h+6\right)-r \geqq \frac{1}{2}\left\{(h-r+1)^{2}-(h-r+1)+6\right\},
$$

which implies that

$$
|K|_{p} \geqq p^{\left((h-r+1)^{2}-(h-r+1)+6\right) / 2}
$$

From the proof of the first part of the theorem, we obtain

$$
|A(K)|_{p} \geqq p^{h-r+1}
$$

Now suppose that $h \geqq r=1$; then

Since $h \geqq 3$, we have

$$
|K|_{p} \geqq p^{\ddagger\left(h^{2}-h+6\right)-1}=p^{\ddagger\left(h^{2}-h+4\right)}
$$

$$
\frac{1}{2}\left(h^{2}-h+4\right) \geqq \frac{1}{2}\left\{(h-1)^{2}-(h-1)+6\right\} .
$$

This gives $|A(K)|_{p} \geqq p^{h-1}$. If $p$ divides $\left|Z(K) \cap K^{\prime}\right|$, then, by Lemma 4.2, we get $|A(G)|_{p}>|A(K)|_{p}$, which gives the desired result. If $\left|Z(K) \cap K^{\prime}\right|_{p}=1$, then we apply Lemma 4.3 to obtain $|A(K)|_{p} \geqq p^{h}$. We have now considered all possible cases and have our main result.

Theorem 4.7. If $|G|_{p} \geqq p^{\left(h^{2}-h+6\right) / 2}$, then $|A(G)|_{p} \geqq p^{h}$.
