#### Abstract

In this paper, we compare the entropy of the original distribution and its corresponding compound distribution. Several results are established based on convex order and relative log-concave order. The necessary and sufficient condition for a compound distribution to be log-concave is also discussed, including compound geometric distribution, compound negative binomial distribution and compound binomial distribution.

## 1. Introduction

The entropy $H(X)$ of a random variable $X$ measures the uncertainty of $X$. In this paper, we only consider discrete random variables. Let $X$ be a discrete random variable with probability mass function (pmf) $\left\{x_{1}, \ldots, x_{n} ; p_{1}, \ldots, p_{n}\right\}$, that is,

$$
p_{i}=\mathbb{P}\left(X=x_{i}\right), \quad i=1, \ldots, n,
$$

with $p_{i} \geq 0, i=1, \ldots, n$, and $\sum_{i=1}^{n} p_{i}=1$. Here, $n$ may be finite or infinite. The Shannon entropy of $X$ is defined by [1]:

$$
H(X)=-\sum_{i=1}^{n} p_{i} \log p_{i} .
$$

The comparisons between distributions with respect to Shannon entropy are regarded as a measure of variability or dispersion. In insurance risk theory, similar comparisons are often established for compound distributions. The random variables corresponding to the compound distributions can be recorded as $S=\sum_{i=1}^{M} X_{i}$, which are extensively used in applied settings. For example, in [3], $S$ can be used to model the total claim amount, $M$ is the number of claims, and the $X_{i}$ are the sizes of claims.

Our results are closely related to those of [8], who established entropy comparison results concerning compound distributions of random variables taking nonnegative integers based on convex ordering and log-concavity. We recall the following definitions. First, denote $\mathbb{N}=\{0,1,2, \ldots\}$.

Definition 1.1. A sequence $\left\{h_{n}, n \in \mathbb{N}\right\}$ is said to be log-concave (LC) if $h_{n} \geq 0$ for $n \in \mathbb{N}$, and

$$
h_{n}^{2} \geq h_{n+1} h_{n-1}, \quad n \geq 1
$$

A log-concave sequence $\left\{h_{n}, n \in \mathbb{N}\right\}$ does not have internal zeros, i.e., there does not exist $i<j<k$ such that $h(i) h(k) \neq 0$ and $h(j)=0$. A random variable $X$ taking values in $\mathbb{N}$ is said to be log-concave, if its $p m f\left\{f_{n}, n \in \mathbb{N}\right\}$ is log-concave.

Definition 1.2. For an integer $n \geq 2$, a positive sequence $\left\{h_{i}, 0 \leq i \leq n\right\}$ is called ultra-log-concave of order $n(\mathrm{ULC}(n))$ if,

$$
\frac{h_{i+1}^{2}}{\binom{n}{i+1}} \geq \frac{h_{i}}{\binom{n}{i}} \frac{h_{i+2}}{\binom{n+2}{i+2}}, \quad 0 \leq i \leq n-2 .
$$

A random variable $X$ taking values in $\mathbb{N}$ is said to be $\operatorname{ULC}(n)$, if its pmf $\left\{f_{i}, 0 \leq i \leq n\right\}$ is $\operatorname{ULC}(n)$. Equivalently, $X$ is $\operatorname{ULC}(n)$ if the sequence $\left\{f_{i} /\binom{n}{i}, 0 \leq i \leq n\right\}$ is log-concave.

Definition 1.3. A random variable $X$ taking values in $\mathbb{N}$ is said to be ultra-log-concave (ULC), if the support of $X$ is an interval on $\mathbb{N}$, and its pmf $\left\{f_{i}, i \in \mathbb{N}\right\}$ satisfies:

$$
(i+1) f_{i+1}^{2} \geq(i+2) f_{i} f_{i+2}, \quad i \geq 0
$$

Equivalently, $X$ is ULC if the sequence $\left\{i!f_{i}, i \in \mathbb{N}\right\}$ is log-concave.
In fact, both $\operatorname{ULC}(n)$ and ULC can be defined in terms of the relative log-concave order ([5]).
Definition 1.4. Let $f$ and $g$ be two pmfs on $\mathbb{N}$. Then $f$ is relative log-concave to $g$, written as $f \leq_{\mathrm{lc}} g$, if
(1) the support of $f$ and $g$ are both intervals on $\mathbb{N}$;
(2) $\operatorname{supp}(f) \subseteq \operatorname{supp}(g)$;
(3) $f_{i} / g_{i}$ is log-concave on $i \in \operatorname{supp}(f)$.

From the above definitions, we have $X \in \operatorname{ULC}(n)$ is equivalent to $X \leq_{\text {lc }} B(n, p)$, and $X \in \operatorname{ULC}$ is equivalent to $X \leq_{\mathrm{lc}} \operatorname{Poi}(\lambda)$, where $p \in(0,1)$ and $\lambda>0$. Also, we have the following inclusion relationship $\mathrm{ULC}(1) \subseteq \mathrm{ULC}(2) \subseteq \cdots \subseteq \mathrm{ULC} \subseteq$ LC.

Definition 1.5. For random variables $X$ and $Y$ on $\mathbb{N}, X$ is smaller than $Y$ in the convex order, written as $X \leq_{\mathrm{cx}} Y$, if $\mathbb{E}[\psi(X)] \leq \mathbb{E}[\psi(Y)]$ for all convex functions $\psi$ on $\mathbb{N}$, provided the expectations exist.

The convex order compares the spread or variability of two distributions. Actually, if $X \leq_{\mathrm{cx}} Y$ and both $X$ and $Y$ have finite means, we have $\mathbb{E}[X]=\mathbb{E}[Y]$ and $\operatorname{Var}(X) \leq \operatorname{Var}(Y)$. Further properties of the convex order can be found in [4]. Since entropy ordering also compares the variability of distributions, it is reasonable to expect some connection with convex ordering. For compound distributions, [7-9] draw the following conclusion.

Theorem 1.1 Suppose $X$ and $Y$ are two absolutely continuous or nonnegative integer-valued random variables.
(1) [8],[9] If $X \leq_{\mathrm{lc}} Y$ and $\mathbb{E}[X]=\mathbb{E}[Y]$, then $X \leq_{\mathrm{cx}} Y$.
(2) [7],[8] If $X \leq_{c x} Y$, and $Y$ has a log-concave pdf or pmf, then $H(X) \leq H(Y)$.

Theorem 1.1 (2) provides a new method to prove entropy inequality. Compared with direct proof, it is relatively easier to establish convex ordering and to verify log-concave condition. Many conclusions in this paper involve Theorem 1.1.

The contributions and the outline of this paper are as follows.
(i) In Section 2, based on Theorem 1.1, we give a direct proof for Lemma 3(2) in [6]. Our proofs are different since [6] constructed a Markov chain whose limiting distribution is a Binomial distribution.
(ii) It is interesting to compare the original distribution and its corresponding compound distribution in the sense of the log-concave order. [8] considered the Poisson and Binomial distributions. Similar result is established in Section 3 for the Negative Binomial distribution.
(iii) [8] obtained the necessary and sufficient conditions for a compound Poisson distribution to be logconcave. In Section 4, we establish necessary and sufficient conditions under which a compound Negative Binomial distribution or a compound Binomial distribution is log-concave.
(iv) The preservation of convex order under compound operation was investigated by [8]. In Section 5, we consider whether the log-concave order is preserved under compound operation.

## 2. The entropy of ULC distribution

Suppose that $\mathscr{F}$ is the set that contains all pmfs for nonnegative integer-valued random variables. Consider two operators $S_{p}$ and $T_{n}$ defined on $\mathscr{F}$ [6]:
(1) For all $p \in(0,1), S_{p}$ maps $\operatorname{pmf} f=\left\{f_{i}, i \in \mathbb{N}\right\}$ to another $\operatorname{pmf} g=\left\{g_{i}, i \in \mathbb{N}\right\}$, where

$$
g_{i}=p f_{i-1}+(1-p) f_{i}, \quad i \geq 0
$$

and define $f_{i}=0$ for all $i<0$. Suppose that $f$ is the pmf of $X, Z \sim B(1, p)$, independent of $X$, then $S_{p} f$ is the pmf of $X+Z$.
(2) For all $n>1, T_{n}$ maps pmf $g=\left\{g_{i}, i=0, \ldots, n\right\}$ to another $\operatorname{pmf} f=\left\{f_{i}, i=0, \ldots, n-1\right\}$, where

$$
\begin{equation*}
f_{i}=\frac{n-i}{n} g_{i}+\frac{i+1}{n} g_{i+1}, \quad i=0, \ldots, n-1 . \tag{2.1}
\end{equation*}
$$

Denote $g$ as the pmf of $Y$. Given $Y$, consider hypergeometric distribution ( $n, Y, n-1$ ), that is, suppose there are $n$ balls in an empty box, in which the number of white balls is $Y$. Now take $n-1$ balls out of the box randomly without putting them back, and define random variable $X$ as the number of white balls in the taken balls. Then $T_{n} g$ is the pmf of $X$.

Operators $S_{p}$ and $T_{n}$ satisfies [6]:
(1) If $b_{n, p}=\{b(i, n, p), i=0, \ldots, n\}$ is the pmf of $B(n, p)$, then

$$
S_{p} b_{n, p}=b_{n+1, p}, \quad T_{n+1} b_{n+1, p}=b_{n, p}, \quad n \geq 1
$$

So, $T_{n+1} \circ S_{p} b_{n, p}=b_{n, p}$.
(2) ULC( $n$ ) contains all the pmfs that are Ultra-log-concave of order $n$. Moreover, we have $S_{p} f \in$ $\operatorname{ULC}(n+1)$ and $T_{n} f \in \operatorname{ULC}(n-1)$ for all $f \in \operatorname{ULC}(n)$.
[6] proved that if $X$ has $\operatorname{pmf} f \in \operatorname{ULC}(n)$ with $\mathbb{E}[X]=n p, p \in(0,1)$, and $Z \sim B(1, p)$, independent of $X$, and if $Y$ is a hypergeometric distribution with parameters $(n+1, X+Z, n)$, then $H(X) \leq H(Y)$. The proof uses the properties of operators $S_{p}$ and $T_{n}$. By constructing a Markov chain whose limiting distribution is $B(n, p)$ and showing that the entropy never decreases along the iterations of this Markov chain. Here, we give another method to prove the non-decreasing property of the corresponding entropy based on Theorem 1.1.

Proposition 2.1. Suppose that $X$ has a pmf $f \in \operatorname{ULC}(n), \mathbb{E}[X]=n p, p \in(0,1), Z \sim B(1, p)$, where $Z$ is independent of $X$. Let $Y$ be a hypergeometric distribution with parameters $(n+1, X+Z, n)$. Then $X \leq \leq_{c x} Y$.

Proof. Define differential operation $\Delta h_{i}=h_{i}-h_{i-1}$ for any sequence $\left\{h_{i}\right\}$, and let $g=\left\{g_{i}, i=0, \ldots, n\right\}$ denote the pmf of $Y$. By (2.1), we have

$$
\begin{equation*}
g_{i}=\frac{n+1-i}{n+1}\left(p f_{i-1}+q f_{i}\right)+\frac{i+1}{n+1}\left(p f_{i}+q f_{i+1}\right), \quad q=1-p . \tag{2.2}
\end{equation*}
$$

Hence,

$$
f_{i}-g_{i}=\frac{1}{n+1} \Delta\left[p(n-i) f_{i}-q(i+1) f_{i+1}\right]=\Delta\left(u_{i} h_{i}\right)
$$

where

$$
u_{i}=p-q \frac{(i+1) f_{i+1}}{(n-i) f_{i}}, \quad h_{i}=\frac{(n-i) f_{i}}{n+1}, \quad 0 \leq i<n
$$

and $u_{i} h_{i}=0, i=-1, n$. Therefore, for any convex function sequence $\psi=\left\{\psi_{i}\right\}$, we have

$$
\mathbb{E}[\psi(Y)]-\mathbb{E}[\psi(X)]=\sum_{i=0}^{n} \psi_{i}\left(g_{i}-f_{i}\right)=-\sum_{i=0}^{n} \psi_{i} \Delta\left(u_{i} h_{i}\right)=\sum_{i=0}^{n-1}\left(\psi_{i+1}-\psi_{i}\right) u_{i} h_{i} .
$$

Since $h_{i} \geq 0$ and $\sum_{i=0}^{n} h_{i}=n q /(n+1), h$ can be modified to a probability function. On the other hand, $f \in \operatorname{ULC}(n)$ means that $u_{i}$ is increasing in $i \in\{0, \ldots, n-1\}$; the convexity of $\psi$ means that $\psi_{i+1}-\psi_{i}$ is increasing in $i$, and $\sum_{i=0}^{n-1} u_{i} h_{i}=0$. Hence, by Chebyshev rearrangement theorem, we have $\sum_{i=0}^{n-1}\left(\psi_{i+1}-\psi_{i}\right) u_{i} h_{i} \geq 0$, that is, $\mathbb{E}[\psi(Y)] \geq \mathbb{E}[\psi(X)]$.

Under the assumptions of Proposition 2.1, $Y \in \operatorname{ULC}(n)$, and the corresponding pmf is log-concave. Hence, by Theorem 1.1, $X \leq_{\text {cx }} Y$ leads to $H(X) \leq H(Y)$.

## 3. Log-concave ordering between the original distribution and its corresponding compound distribution

Suppose that $S$ is a nonnegative integer-valued random variable, defined by:

$$
S=\sum_{i=1}^{M} X_{i}
$$

where $\left\{X_{n}, n \geq 1\right\}$ is a sequence of independent and identically distributed (iid) nonnegative integervalued random variables, and $M$ is a counting random variable independent of all $X_{i}$ 's. Let $f$ and $h$ be the pmfs of $X_{i}$ and $M$, respectively. The distribution of $S$ is called a compound distribution with its pmf denoted by $c_{h}(f)$. If $M \sim \operatorname{Poi}(\lambda), B(n, p)$ or $\mathrm{NB}(\alpha, p)$, then the distribution of $S$ is called compound Poisson distribution, compound Binomial distribution or compound Negative Binomial distribution. For $\alpha=1, \mathrm{NB}(1, p)$ reduces to the geometric distribution $\operatorname{Geo}(p)$.

In the following, the pmfs of $\operatorname{Poi}(\lambda), \mathrm{B}(n, p), \mathrm{NB}(\alpha, p)$ and $\operatorname{Geo}(p)$ distributions are denoted by poi $(\lambda), \mathrm{b}(n, p), \mathrm{nb}(\alpha, p)$ and geo $(p)$, respectively. Similarly, the pmfs of the corresponding compound distributions are denoted by $c_{\mathrm{poi}(\lambda)}(f), c_{\mathrm{b}(n, p)}(f), c_{\mathrm{nb}(\alpha, p)}(f)$ and $c_{\mathrm{geo}(p)}(f)$. Denote by $\mu_{f}$ the mean of a distribution with pmf $f$. Then the means of the distributions with pmf $c_{\mathrm{poi}(\lambda)}(f), c_{\mathrm{b}(n, p)}(f)$, $c_{\mathrm{nb}(\alpha, p)}(f)$ are $\lambda \mu_{f}, n p \mu_{f}$ and $\alpha(1-p) \mu_{f} / p$, respectively.

Proposition 3.1. ([8]) Let f be a pmf on $\mathbb{N}$.
(1) If the compound Poisson distribution $c_{\mathrm{poi}(\lambda)}(f)$ is non-degenerate and log-concave, and $\lambda, \lambda^{*}>0$, then $\operatorname{poi}\left(\lambda^{*}\right) \leq_{\mathrm{lc}} c_{\mathrm{poi}(\lambda)}(f)$.
(2) If the compound Binomial distribution $c_{\mathrm{b}(n, p)}(f)$ is non-degenerate and $\log$-concave, and $p, p^{*} \in$ $(0,1)$, then $\mathrm{b}\left(n, p^{*}\right) \leq_{\mathrm{lc}} c_{\mathrm{b}(n, p)}(f)$.

By Theorem 1.1 and Proposition 3.1, we have

$$
\begin{align*}
& \lambda^{*}=\lambda \mu_{f} \Longrightarrow H\left(\operatorname{poi}\left(\lambda^{*}\right)\right) \leq H\left(c_{\mathrm{poi}(\lambda)}(f)\right),  \tag{3.1}\\
& p^{*}=p \mu_{f} \Longrightarrow H\left(\mathrm{~b}\left(n, p^{*}\right)\right) \leq H\left(c_{\mathrm{b}(n, p)}(f)\right) . \tag{3.2}
\end{align*}
$$

Here, $\lambda^{*}=\lambda \mu_{f}$ ensures that two pmfs poi $\left(\lambda^{*}\right)$ and $c_{\text {poi }(\lambda)}(f)$ have the same mean. Similarly, $p^{*}=$ $p \mu_{f}$ ensures that two pmfs $\mathrm{b}\left(n, p^{*}\right)$ and $c_{\mathrm{b}(n, p)}(f)$ have the same mean. Suppose that $M \sim \mathrm{~B}(n, p)$, $M^{*} \sim \mathrm{~B}\left(n, p^{*}\right)$, and $\left\{X_{i}, i \geq 1\right\}$ are iid random variables with a common $\mathrm{pmf} f$. Assume that all random variables considered here and below are independent of each other. The explanation of (3.2) is as follows, and the explanation of (3.1) can be given similarly. We consider two following cases:
(i) Suppose $\mu_{f} \geq 1$. Then $p^{*} \geq p$ since $p^{*}=p \mu_{f}$ in (3.2). Let $\left\{I_{i}, i \geq 1\right\}$ be a sequence of iid Bernoulli random variables with $\mathbb{P}\left(I_{i}=1\right)=p / p^{*} \in(0,1]$. Since $\sum_{i=1}^{M^{*}} I_{i}$ has the same distribution as $M$, it follows that the pmf of $\sum_{i=1}^{M^{*}} I_{i} X_{i}$ is $c_{\mathrm{b}\left(n, p^{*}\right)}(\tilde{f})=c_{\mathrm{b}(n, p)}(f)$, where $\tilde{f}$ is the pmf of $I_{i} X_{i}$, given by:

$$
\tilde{f}=\frac{p}{p^{*}} f+\left(1-\frac{p}{p^{*}}\right) \delta_{0}
$$

where $\delta_{0}$ is the pmf of a degenerate random variable $Z=0$. Notice that $\mu_{\tilde{f}}=p \mu_{f} / p^{*}=1$, and the uncertainty of $\sum_{i=1}^{M^{*}} I_{i} X_{i}$ is obviously stronger than that of $M^{*}$. Thus, (3.2) holds.
(ii) Suppose $\mu_{f} \in(0,1)$. In this case, $p^{*}<p$. Let $\left\{I_{i}, i \geq 1\right\}$ be a sequence of iid Bernoulli random variables with $\mathbb{P}\left(I_{i}=1\right)=p^{*} / p \in(0,1]$. Then $\sum_{i=1}^{M} I_{i} \sim \mathrm{~B}\left(n, p^{*}\right)$, and the pmf of $\sum_{i=1}^{M} X_{i}$ is $c_{\mathrm{b}(n, p)}(f)$. Note that $\mathbb{E}\left[I_{i}\right]=\mathbb{E}\left[X_{i}\right]=p^{*} / p$ and $I_{i} \leq_{\mathrm{cx}} X_{i}$ for each $i$. Thus, the uncertainty of $\sum_{i=1}^{M} X_{i}$ is obviously stronger than $\sum_{i=1}^{M} I_{i}$, that is (3.2).

To obtain the similar result for a compound Negative Binomial distribution, we need the recursive expression for the corresponding pmf.

Lemma 3.2. Denote the pmf of $c_{\mathrm{nb}(\alpha, p)}(f)$ as $g$. Then

$$
\begin{equation*}
(n+1) g_{n+1}=\frac{q}{1-q f_{0}} \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha] f_{j+1} g_{n-j}, \quad n \geq 0 \tag{3.3}
\end{equation*}
$$

Proof. In [3], it is assumed that $f_{0}=0$. We consider a more general situation, $f_{0} \geq 0$. The pmf of $\mathrm{NB}(\alpha, p)$ is denoted by $\left\{p_{n}, n \geq 0\right\}$, that is

$$
p_{n}=\binom{\alpha+n-1}{n} p^{\alpha} q^{n}, \quad n \geq 0, q=1-p
$$

so

$$
\frac{p_{n}}{p_{n-1}}=a+\frac{b}{n}, \quad n \geq 1,
$$

where $a=q, b=(\alpha-1) q$. Hence, for all $n \geq 0$,

$$
\begin{equation*}
\sum_{j=0}^{n+1}\left(a+\frac{b j}{n+1}\right) f_{j} g_{n+1-j}=q f_{0} g_{n+1}+\frac{q}{n+1} \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha] f_{j+1} g_{n-j} \tag{3.4}
\end{equation*}
$$

Denote by $f^{(k)}=\left\{f_{i}^{(k)}, i \in \mathbb{N}\right\}$ the pmf of $\sum_{i=1}^{k} X_{i}$, where $X_{1}, \ldots, X_{k}$ are iid random variables with a common $\operatorname{pmf} f$. On the other hand, by using $\sum_{j=0}^{n+1} j f_{j} f_{n+1-j}^{(k)}=\frac{n+1}{k+1} f_{n+1}^{(k+1)}$, we have

$$
\begin{align*}
\sum_{j=0}^{n+1}\left(a+\frac{b j}{n+1}\right) f_{j} g_{n+1-j} & =\sum_{j=0}^{n+1}\left(a+\frac{b j}{n+1}\right) f_{j} \sum_{k=0}^{\infty} p_{k} f_{n+1-j}^{(k)} \\
& =\sum_{k=0}^{\infty} p_{k} \sum_{j=0}^{n+1}\left(a+\frac{b j}{n+1}\right) f_{j} f_{n+1-j}^{(k)} \\
& =\sum_{k=0}^{\infty} p_{k}\left(a f_{n+1}^{(k+1)}+\frac{b}{n+1} \sum_{j=0}^{n+1} i f_{j} f_{n+1-j}^{(k)}\right) \\
& =\sum_{k=0}^{\infty} p_{k}\left(a+\frac{b}{k+1}\right) f_{n+1}^{(k+1)} \\
& =\sum_{k=1}^{\infty} p_{k} f_{n+1}^{(k)} \\
& =p_{0} f_{n+1}^{(0)}+\sum_{k=1}^{\infty} p_{k} f_{n+1}^{(k)} \quad\left[f_{\ell}^{(0)}=0, \ell \geq 1\right] \\
& =g_{n+1} . \tag{3.5}
\end{align*}
$$

By (3.4) and (3.5), we conclude (3.3).

Proposition 3.3. Let $f$ be a pmf defined on $\mathbb{N}$. If $\alpha^{*} \geq \alpha \in(0,1], p, p^{*} \in(0,1)$, and if the compound Negative Binomial distribution $c_{\mathrm{nb}(\alpha, p)}(f)$ is non-degenerate and log-concave, then $\mathrm{nb}\left(\alpha^{*}, p^{*}\right) \leq_{\mathrm{lc}}$ $c_{\mathrm{nb}(\alpha, p)}(f)$.

Proof. Denote $g=c_{\mathrm{nb}(\alpha, p)}(f)$. Since $g$ is non-degenerate and log-concave, we have $g_{n}>0$ for $n \in \mathbb{N}$ and

$$
\begin{equation*}
\frac{g_{n-j}}{g_{n-j-1}} \geq \frac{g_{n}}{g_{n-1}}, \quad 0<j<n \tag{3.6}
\end{equation*}
$$

Since $\alpha \in(0,1)$ and $\alpha^{*} \geq \alpha$, it follows that:

$$
\begin{equation*}
\frac{(\alpha-1) j+n+\alpha}{(\alpha-1) j+n-1+\alpha} \geq \frac{n+\alpha}{n+\alpha-1} \geq \frac{n+\alpha^{*}}{n+\alpha^{*}-1}, \quad j \geq 1 \tag{3.7}
\end{equation*}
$$

In view of (3.6) and (3.7), we have

$$
\begin{aligned}
(n+1) g_{n+1} & \geq \frac{q}{1-q f_{0}} \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha] f_{j+1} g_{n-j-1} \cdot \frac{g_{n}}{g_{n-1}} \\
& \geq \frac{g_{n}}{g_{n-1}} \cdot \frac{q}{1-q f_{0}} \sum_{j=0}^{n-1}[(\alpha-1) j+n+\alpha] f_{j+1} g_{n-j-1} \\
& \geq \frac{g_{n}}{g_{n-1}} \cdot \frac{q}{1-q f_{0}} \sum_{j=0}^{n-1}[(\alpha-1) j+n-1+\alpha] \frac{\alpha^{*}+n}{\alpha^{*}+n-1} f_{j+1} g_{n-j-1} \\
& \geq \frac{g_{n}\left(\alpha^{*}+n\right)}{g_{n-1}\left(\alpha^{*}+n-1\right)} \cdot \frac{q}{1-q f_{0}} \sum_{j=0}^{n-1}[(\alpha-1) j+(n-1)+\alpha] f_{j+1} g_{n-j-1} \\
& =\frac{g_{n}\left(\alpha^{*}+n\right)}{g_{n-1}\left(\alpha^{*}+n-1\right)} \cdot n g_{n}, \quad n \geq 1 .
\end{aligned}
$$

The above inequality can be simplified to:

$$
\left[\frac{g_{n}}{\binom{\alpha^{*}+n-1}{n}}\right]^{2} \leq \frac{g_{n-1}}{\binom{\alpha^{*}+n-2}{n-1}} \cdot \frac{g_{n+1}}{\binom{\alpha^{*}+n}{n+1}}, \quad n \geq 1,
$$

that is, $g_{n} /\binom{\alpha^{*}+n-1}{n}$ is log-convex, $\operatorname{sonb}\left(\alpha^{*}, p^{*}\right) \leq_{\text {lc }} g$.
Corollary 3.4. Suppose that $f$ is a pmf defined on $\mathbb{N}$ with the mean $\mu>0$. For $\alpha \in(0,1]$, if there exists $\alpha^{*}>\alpha$ and $p^{*} \in(0,1)$ such that:

$$
\frac{\alpha^{*}\left(1-p^{*}\right)}{p^{*}}=\frac{\alpha \mu(1-p)}{p},
$$

and $c_{\mathrm{nb}(\alpha, p)}(f)$ is non-degenerate and log-concave, then $H\left(\operatorname{nb}\left(\alpha^{*}, p^{*}\right)\right) \leq H\left(c_{\mathrm{nb}(\alpha, p)}(f)\right)$.
Proof. By Proposition 3.3, $\mathrm{nb}\left(\alpha^{*}, p^{*}\right) \leq_{\mathrm{lc}} c_{\mathrm{nb}(\alpha, p)}(f)$. It is easy to verify that the means of $\mathrm{nb}\left(\alpha^{*}, p^{*}\right)$ and $c_{\mathrm{nb}(\alpha, p)}(f)$ are equal. Thus, the desired result follows from Theorem 1.1(1) directly.

Proposition 3.5. Suppose that $\alpha>0$ and $p \in(0,1)$. If $c_{\mathrm{nb}(\alpha, p)}(f)$ is non-degenerate and log-concave, then $\operatorname{poi}(\lambda) \leq_{\operatorname{lc}} c_{\mathrm{nb}(\alpha, p)}(f)$ for any $\lambda>0$. In particular, when $\lambda^{*}=\alpha \mu(1-p) / p$, we have $H\left(\operatorname{poi}\left(\lambda^{*}\right)\right) \leq$ $H\left(c_{\mathrm{nb}(\alpha, p)}(f)\right)$.

Proof. The notations are the same as in the proof of Proposition 3.3. Obviously, $g_{n}>0$ for $n \geq 0$ and by the log-concavity of $g$, we have

$$
\frac{g_{n-j}}{g_{n+1-j}} \leq \frac{g_{n}}{g_{n+1}}, \quad j=0, \ldots, n
$$

Hence, for $n \geq 0$,

$$
\begin{aligned}
(n+1) g_{n+1} & \leq \frac{q}{1-q f_{0}} \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha] f_{j+1} g_{n+1-j} \cdot \frac{g_{n}}{g_{n+1}} \\
& \leq \frac{g_{n}}{g_{n+1}} \cdot \frac{q}{1-q f_{0}} \sum_{j=0}^{n+1}[(\alpha-1) j+n+1+\alpha] f_{j+1} g_{n+1-j}
\end{aligned}
$$

$$
=\frac{g_{n}}{g_{n+1}} \cdot(n+2) g_{n+2},
$$

that is, $n!g_{n}$ is log-convex in $n \in \mathbb{N}$. Thus, $\operatorname{poi}(\lambda) \leq_{\operatorname{lc}} c_{\mathrm{nb}(\alpha, p)}(f)$. The rest can be derived directly from Theorem 1.1.

## 4. Log-concavity of a compound distribution

[8] proved that if $f$ is log-concave, then $c_{\text {poi }(\lambda)}(f)$ is log-concave if and only if $\lambda f_{1}^{2} \geq 2 f_{2}$. In order to show that Propositions 3.3, 3.5 and Corollary 3.4 are meaningful, we need to investigate the logconcavity of compound Negative Binomial distribution. Firstly, we study the necessary and sufficient condition for a compound Geometric distribution to be log-concave.

Proposition 4.1. Suppose $f$ is a pmf defined on $\mathbb{N}$ such that $f_{1}>0$. For $p \in(0,1)$, we have $c_{\operatorname{geo}(p)}(f) \in$ LC if and only if $f_{k}=0$ for all $k \geq 2$.

Proof. Denote the pmf of $\operatorname{Geo}(p)$ as $\left\{p_{n}, n \geq 0\right\}$. Then the $\operatorname{pmf}$ of $c_{\operatorname{geo}(p)}(f)$ is $g$. By (3.3), we have:

$$
\begin{equation*}
g_{n+1}=\eta \sum_{j=0}^{n} f_{j+1} g_{n-j}, \quad n \geq 0 \tag{4.1}
\end{equation*}
$$

where $\eta=q /\left(1-q f_{0}\right)>0$.
First of all, observe that
(1) $g_{0}=p_{0}+\sum_{n=1}^{\infty} p_{n} f_{0}^{n}=p+\sum_{n=1}^{\infty} p q^{n} f_{0}^{n}=p /\left(1-q f_{0}\right)=p \eta / q>0$;
(2) $f_{1} \neq 0 \Longrightarrow g_{n}>0$ for $n \geq 0$.
$(\Longrightarrow)$ Prove that $f_{n}=0$ for all $n \geq 2$ by induction. For $n=2$, by (4.1), we have $g_{1}=\eta f_{1} g_{0}, g_{2}=$ $\eta\left[f_{1} g_{1}+f_{2} g_{0}\right]$. Substituting in $g_{1}^{2} \geq g_{0} g_{2}$, we have $f_{2} g_{0}=0$, that is, $f_{2}=0$ and $g_{1}^{2}=g_{0} g_{2}$.

Now assume that $f_{n}=0$ for $n=2, \cdots, k$ and $g_{k-1}^{2}=g_{k-2} g_{k}$. Notice that

$$
g_{k-1}=\eta f_{1} g_{k-2}, g_{k}=\eta f_{1} g_{k-1}, g_{k+1}=\eta\left[f_{1} g_{k}+f_{k+1} g_{0}\right] .
$$

Substituting in $g_{k}^{2} \geq g_{k-1} g_{k+1}$, we have

$$
f_{1}^{2} g_{k-1}^{2} \geq f_{1}^{2} g_{k} g_{k-2}+f_{1} f_{k+1} g_{0} g_{k-2}
$$

So, $f_{1} f_{k+1} g_{0} g_{k-2}=0$. Thus, $f_{k+1}=0$ and in the meantime, $g_{k}^{2}=g_{k-1} g_{k+1}$. The necessity is proved by induction.
$(\Longleftarrow)$ Suppose that $f_{k}=0$ for all $k \geq 2$. By (4.1), we have

$$
\begin{equation*}
g_{n+1}=\eta f_{1} g_{n}=\left(\eta f_{1}\right)^{n+1} g_{0}, \quad n \geq 0 \tag{4.2}
\end{equation*}
$$

It is obvious that $g_{n}^{2}=g_{n-1} g_{n+1}$ for $n \geq 1$ and, hence, $g \in \mathrm{LC}$.

## Remark 4.2.

(1) By (4.2), we have

$$
c_{\operatorname{geo}(p)}(f) \in \mathrm{LC} \Longrightarrow c_{\operatorname{geo}(p)}(f)=\operatorname{geo}\left(\frac{p}{1-q f_{0}}\right)
$$

(2) Assume that $f_{n}=0$ for $n \geq 2$ with $f_{1}>0$. Then $g:=c_{\mathrm{nb}(\alpha, p)}(f) \in \mathrm{LC}$ if and only if $\alpha \geq 1$. In fact, if $f_{n}=0$ for $n \geq 2$, then (3.3) can be simplified to:

$$
g_{n+1}=\frac{n+\alpha}{n+1} \eta f_{1} g_{n}, \quad n \geq 0
$$

It is easy to verify that

$$
g_{n+1}^{2} \geq g_{n} g_{n+2} \Longleftrightarrow \frac{\alpha-1}{n+1} \geq \frac{\alpha-1}{n+2}
$$

that is, $\alpha \geq 1$.

Proposition 4.3. Suppose that $f \in \mathrm{LC}$, and denote $q=1-p$ and $\eta=q /\left(1-q f_{0}\right)$. Then $g:=c_{\mathrm{nb}(\alpha, p)}(f) \in$ LC if and only if

$$
\begin{equation*}
(\alpha-1) \eta f_{1}^{2} \geq 2 f_{2} \tag{4.3}
\end{equation*}
$$

The proof of Proposition 4.3 is postponed to Appendix A.1.
Remark 4.4. Suppose that $f \in \mathrm{LC}, 0<\alpha \leq \alpha^{*}$ and $p \geq p^{*}>0$. If $g:=c_{\mathrm{nb}(\alpha, p)}(f) \in \mathrm{LC}$, then $c_{\mathrm{nb}\left(\alpha^{*}, p^{*}\right)}(f) \in \mathrm{LC}$.

Next, the necessary and sufficient condition for a compound Binomial distribution to be log-concave is discussed. To this end, we first give the recursive expression of its corresponding pmf.

Lemma 4.5. Denote $g:=c_{\mathrm{b}(n, p)}(f)$. Then the pmf $\left\{g_{k}, k \in \mathbb{N}\right\}$ has recursive expression as follows:

$$
\begin{equation*}
(k+1) g_{k+1}=\delta \sum_{j=0}^{k}[(n+1) j+n-k] f_{j+1} g_{k-j}, \quad k \geq 0, \tag{4.4}
\end{equation*}
$$

where $\delta=p /\left(p f_{0}+q\right)$ and $q=1-p$.
Proof. The proof of (4.4) is similar to (3.3) since

$$
\frac{p_{k}}{p_{k-1}}=-\frac{p}{q}+\frac{(n+1) p}{q k}=a+\frac{b}{k}, \quad \forall k \geq 1
$$

Here, (3.5) still holds,

$$
\begin{equation*}
\sum_{j=0}^{k+1}\left(a+\frac{b j}{k+1}\right) f_{j} g_{k+1-j}=g_{k+1}, k \geq 0 \tag{4.5}
\end{equation*}
$$

and (3.4) is replaced by the following formula

$$
\begin{align*}
& \sum_{j=0}^{k+1}\left(a+\frac{b j}{k+1}\right) f_{j} g_{k+1-j} \\
& \quad=-\frac{p}{q} f_{0} g_{n+1}+\frac{p}{q(n+1)} \sum_{j=0}^{k}[(n+1) j+n-k] f_{j+1} g_{k-j}, \quad k \geq 0 \tag{4.6}
\end{align*}
$$

Thus, (4.4) follows from (4.5) and (4.6).

Proposition 4.6. Denote $g:=c_{\mathrm{b}(n, p)}(f)$, and let $f \in \mathrm{LC}$. If $g \in \mathrm{LC}$, then

$$
\begin{equation*}
(n+1) \delta f_{1}^{2} \geq 2 f_{2} \tag{4.7}
\end{equation*}
$$

where $\delta=p /\left(p f_{0}+q\right)$ and $q=1-p$. In particular, for $n=1$, (4.7) is also the sufficient condition for $c_{\mathrm{b}(1, p)}(f) \in \mathrm{LC}$. But for $n \geq 2$, (4.7) is not the sufficient condition for $g \in \mathrm{LC}$.

Proof. (1) By lemma 4.5, we have $g_{1}=n \delta f_{1} g_{0}$ and $g_{2}=\left[(n-1) \delta f_{1} g_{1}+2 n \delta f_{2} g_{0}\right] / 2$. In view of $g_{1}^{2} \geq g_{0} g_{2}$, we obtain (4.7).
(2) For $n=1$, (4.7) holds, that is $\delta f_{1}^{2} \geq f_{2}$. Based on the random expression of the random variable corresponding to $g$, we have $g_{0}=q+p f_{0}$ and $g_{k}=p f_{k}$ for $k \geq 1$. To prove $g \in \mathrm{LC}$, we only need to prove $g_{1}^{2} \geq g_{0} g_{2}$, that is, (4.7).
(3) Take a counterexample to illustrate: assume $n=2$, and $c_{\mathrm{b}(2, p)}(f)=c_{\mathrm{b}(1, p)}(f) * c_{\mathrm{b}(1, p)}(f)$. Denote $h=c_{\mathrm{b}(1, p)}(f)$, by (2), we have $h_{0}=q+p f_{0}, h_{k}=p f_{k}, k \geq 1$. Especially, take $p=20 / 23$,

$$
f=\left(\frac{1}{20}, \frac{1}{5}, \frac{3}{10}, \frac{9}{20}, 0,0, \cdots\right) .
$$

Then

$$
h=\left(\frac{4}{23}, \frac{4}{23}, \frac{6}{23}, \frac{9}{23}, 0,0, \cdots\right) .
$$

Hence,

$$
g=h * h=\left(g_{0}, g_{1}, g_{2}, \frac{120}{23^{2}}, \frac{108}{23^{2}}, \frac{108}{23^{2}}, g_{6}, \cdots\right) .
$$

Obviously, $g_{4}^{2}<g_{3} g_{5}$, which means that $g$ is not log-concave. On the other hand, $\delta=p /\left(p f_{0}+q\right)=5$, $f \in \mathrm{LC}$, and $3 \delta f_{1}^{2}=3 / 5=2 f_{2}$, that is (4.7) holds. Therefore, (4.7) is not the sufficient condition for $g \in \mathrm{LC}$.

## 5. The relative log-concavity

Lemma 2 in [8] states that, for pmfs $f, g, f^{*}$ and $g^{*}$ defined on $\mathbb{Z}_{+}$, if $f \leq_{\mathrm{cx}} f^{*}$ and $g \leq_{\mathrm{cx}} g^{*}$, then $c_{g}(f) \leq_{\mathrm{cx}} c_{g^{*}}\left(f^{*}\right)$. On the other hand, $g \leq_{\text {lc }}$ poi $(\lambda)$ for any $g \in$ ULC and $\lambda>0$. Connected with Theorem 1.1, it is easy to establish the following proposition.

## Proposition 5.1.

(1) [8] If $g \in \operatorname{ULC}$ and $\mu_{g}=\lambda$, then $c_{g}(f) \leq_{\mathrm{cx}} c_{\mathrm{poi}(\lambda)}(f)$.
(2) [8],[2] If $g \in \mathrm{ULC}, \mu_{g}=\lambda>0$ and $c_{\mathrm{poi}(\lambda)}(f) \in \mathrm{LC}$, then $H\left(c_{g}(f)\right) \leq H\left(c_{\mathrm{poi}(\lambda)}(f)\right)$.

Notice that $g \in \operatorname{ULC}(n) \Longleftrightarrow g \leq_{\mathrm{lc}} b(n, p)$ for all $p \in(0,1)$, and that $g \in \operatorname{LC} \Longleftrightarrow g \leq_{\mathrm{lc}} \operatorname{geo}(\lambda)$ for all $\lambda>0$. The following two propositions are easily established by Theorem 1.1.

## Proposition 5.2.

(1) If $g \in \operatorname{ULC}(n)$ and $\mu_{g}=n p$, then $c_{g}(f) \leq_{\mathrm{cx}} c_{\mathrm{b}(n, p)}(f)$.
(2) If $g \in \operatorname{ULC}(n), \mu_{g}=n p$ and $c_{\mathrm{b}(n, p)}(f) \in \mathrm{LC}$, then $H\left(c_{g}(f)\right) \leq H\left(c_{\mathrm{b}(n, p)}(f)\right)$.

## Proposition 5.3.

(1) If $g \in \operatorname{LC}$ and $\mu_{g}=(1-\lambda) / \lambda$, then $c_{g}(f) \leq_{\mathrm{cx}} c_{\mathrm{geo}(\lambda)}(f)$.
(2) If $g \in \operatorname{LC}, \mu_{g}=(1-\lambda) / \lambda$ and $c_{\operatorname{geo}(\lambda)}(f) \in \mathrm{LC}$, then $H\left(c_{g}(f)\right) \leq H\left(c_{\operatorname{geo}(\lambda)}(f)\right.$.

Naturally, the following problems will arise:
Question
(1) If $g \in \operatorname{ULC}$ and $\mu_{g}=\lambda$, is it correct $c_{g}(f) \leq_{\mathrm{lc}} c_{\mathrm{poi}(\lambda)}(f)$ ?
(2) If $g \in \operatorname{ULC}(n)$ and $\mu_{g}=n p$, is it correct $c_{g}(f) \leq_{\text {lc }} c_{\mathrm{b}(n, p)}(f)$ ?
(3) If $g \in \operatorname{LC}$ and $\mu_{g}=(1-\lambda) / \lambda$, is it correct that $c_{g}(f) \leq_{\operatorname{lc}} c_{\operatorname{geo}(\lambda)}(f)$ ?

The following three counterexamples show that the assertions in Question 1 are negative.
Example 5.1. $g \in \mathrm{ULC}, \mu_{g}=\lambda$ and $f \in \mathrm{LC} \nRightarrow c_{g}(f) \leq_{\mathrm{lc}} c_{\mathrm{poi}(\lambda)}(f)$.
Suppose that $g=B(2, \lambda / 2)$ and $0<\lambda<2, f$ satisfies $f_{j}=0$ for $j \geq 3$, and denote $s=c_{g}(f)$ and $t=c_{\mathrm{poi}(\lambda)}(f)$. Then

$$
\begin{aligned}
& s_{0}=\left(1-\frac{\lambda}{2}\right)^{2}+\lambda\left(1-\frac{\lambda}{2}\right) f_{0}+\frac{\lambda^{2}}{4} f_{0}^{2}, \quad s_{1}=\lambda\left(1-\frac{\lambda}{2}\right) f_{1}+\frac{\lambda^{2}}{2} f_{0} f_{1}, \\
& s_{2}=\lambda\left(1-\frac{\lambda}{2}\right) f_{2}+\frac{\lambda^{2}}{2} f_{0} f_{2}+\frac{\lambda^{2}}{4} f_{1}^{2}, \quad s_{3}=\frac{\lambda^{2}}{2} f_{1} f_{2}, \quad s_{4}=\frac{\lambda^{2}}{4} f_{2}^{2},
\end{aligned}
$$

and

$$
\begin{aligned}
t_{0} & =e^{\lambda\left(f_{0}-1\right)}, \quad t_{1}=\lambda f_{1} e^{\lambda\left(f_{0}-1\right)}, \quad t_{2}=\frac{\lambda}{2}\left(\lambda f_{1}^{2}+2 f_{2}\right) e^{\lambda\left(f_{0}-1\right)}, \\
t_{3} & =\lambda^{2} f_{1}\left(\frac{1}{6} \lambda f_{1}^{2}+f_{2}\right) e^{\lambda\left(f_{0}-1\right)}, \quad t_{4}=\frac{\lambda^{2}}{4}\left(\frac{1}{6} \lambda^{2} f_{1}^{4}+2 \lambda f_{1}^{2} f_{2}+2 f_{2}^{2}\right) e^{\lambda\left(f_{0}-1\right)} .
\end{aligned}
$$

Especially, we take $\lambda=1$ and $f=\left(f_{0}, f_{1}, f_{2}\right)=(1 / 3,1 / 3,1 / 3)$, that is, $f$ is a discrete uniform distribution on $\{0,1,2\}$. Obviously, $f \in$ ULC. By calculation,

$$
\left(\frac{s_{0}}{t_{0}}, \frac{s_{1}}{t_{1}}, \frac{s_{2}}{t_{2}}, \frac{s_{3}}{t_{3}}, \frac{s_{4}}{t_{4}}\right)=\left(\frac{4}{9}, \frac{2}{3}, \frac{9}{14}, \frac{9}{19}, \frac{54}{145}\right) e^{2 / 3} .
$$

It can be verified that

$$
\left(\frac{s_{1}}{t_{1}}\right)^{2}-\frac{s_{0}}{t_{0}} \frac{s_{2}}{t_{2}}>0, \quad\left(\frac{s_{3}}{t_{3}}\right)^{2}-\frac{s_{2}}{t_{2}} \frac{s_{4}}{t_{4}}=-0.015<0
$$

Hence, $s_{k} / t_{k}$ is not log-concave, so $s \not \bigsqcup_{\mathrm{lc}} t$.
Example 5.2. $g \in \mathrm{LC}, \mu_{g}=(1-\lambda) / \lambda$ and $f \in \mathrm{LC} \nRightarrow c_{g}(f) \leq_{\mathrm{lc}} c_{\text {geo }(\lambda)}(f)$.
Suppose that $f$ and $g$ satisfy $f_{j}=g_{j}=0$ for $j \geq 3$, and denote $s=c_{g}(f)$ and $t=c_{\text {geo }}(f)$. Then

$$
\begin{aligned}
& s_{0}=g_{0}+g_{1} f_{0}+g_{2} f_{0}^{2}, \quad s_{1}=g_{1} f_{1}+2 g_{2} f_{0} f_{1}, \\
& s_{2}=g_{1} f_{2}+g_{2}\left(2 f_{0} f_{2}+f_{1}^{2}\right), \quad s_{3}=2 g_{2} f_{1} f_{2}, \quad s_{4}=g_{2} f_{2}^{2},
\end{aligned}
$$

and

$$
t_{1}=\eta f_{1} t_{0}, \quad t_{2}=\eta\left(f_{1} t_{1}+f_{2} t_{0}\right), \quad t_{3}=\eta\left(f_{1} t_{2}+f_{2} t_{1}\right), \quad t_{4}=\eta\left(f_{1} t_{3}+f_{2} t_{2}\right)
$$

with $\eta=(1-\lambda) /\left[1-(1-\lambda) f_{0}\right]$. If we take $f=\left(f_{0}, f_{1}, f_{2}\right)=(1 / 3,1 / 3,1 / 3) \in \operatorname{LC}$, then

$$
g=\left(g_{0}, g_{1}, g_{2}\right)=\left(\frac{7 \lambda-3}{4 \lambda}, \frac{1-\lambda}{2 \lambda}, \frac{1-\lambda}{4 \lambda}\right) .
$$

Given $\lambda=40 / 77, g$ is log-concave, that is, $g \leq_{\text {lc }} \operatorname{Geo}(\lambda)$. It is easy to verify that

$$
\left(\frac{s_{3}}{t_{3}}\right)^{2}-\frac{s_{2}}{t_{2}} \frac{s_{4}}{t_{4}}=-0.082<0
$$

hence, $s_{k} / t_{k}$ is not log-concave, so $s \not \not_{\mathrm{lc}} t$.

Example 5.3. $g \in \operatorname{ULC}(n), \mu_{g}=n p, p \in(0,1)$ and $f \in \operatorname{LC} \nRightarrow c_{g}(f) \leq_{\mathrm{lc}} c_{\mathrm{b}(n, p)}(f)$.
Suppose that $f=\left(f_{0}, f_{1}, f_{2}\right)=(1 / 3,1 / 3,1 / 3) \in \mathrm{LC}$ and $g=\left(g_{0}, g_{1}, g_{2}\right)=(1-3 p / 2, p, p / 2)$. If $p \in(1 / 2,2 / 3)$, then $g \in \operatorname{ULC}(2)$. Denote $s=c_{g}(f)$ and $t=c_{\mathrm{b}(2, p)}(f)$. Then $s_{j}$ and $t_{j}$ can be calculated as in Example 5.2. Choose $p=7 / 12$. Then

$$
\left(\frac{s_{3}}{t_{3}}\right)^{2}-\frac{s_{2}}{t_{2}} \frac{s_{4}}{t_{4}}=-0.1728<0
$$

hence, $s_{k} / t_{k}$ is not log-concave, so $s \not \coprod_{\mathrm{lc}} t$.

## Appendix A. Proof of Proposition 4.3

Proof. For reading convenience, use $P=g$ as pmf, and set $P_{i}=0$ for $i<0$. Denote $r_{j}=\eta f_{j+1}$, and rewrite (3.3) as:

$$
\begin{equation*}
(n+1) P_{n+1}=\sum_{j=0}^{n}[(\alpha-1) j+n+\alpha] r_{j} P_{n-j}, \quad \forall n \geq 0 \tag{A.1}
\end{equation*}
$$

$(\Longrightarrow) B y(A .1)$, we have $P_{1}=\alpha r_{0} P_{0}, P_{2}=\left[(1+\alpha) r_{0} P_{1}+2 \alpha r_{1} P_{0}\right] / 2$. Since $P \in \mathrm{LC}$, it follows that $P_{1}^{2} \geq P_{0} P_{1}$, and thus,

$$
P_{1} \cdot \alpha r_{0} P_{0} \geq \frac{1}{2}\left[(1+\alpha) r_{0} P_{1}+2 \alpha r_{1} P_{0}\right] P_{0}
$$

So (4.3) can be proved directly by simplify the above equation.
( $\Longleftarrow)$ Suppose (4.3) holds. First, notice the following equations:

$$
\begin{aligned}
\alpha P_{n} P_{n+1}= & \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha](n+\alpha) r_{j} P_{n-j} P_{n} \\
& -\sum_{j=0}^{n-1}[(\alpha-1) j+n-1+\alpha](n+1+\alpha) r_{j} P_{n-1-j} P_{n+1}, \\
(n+1)^{2} P_{n+1}^{2}= & \sum_{k=0}^{n} \sum_{l=0}^{n}[(\alpha-1) k+n+\alpha][(\alpha-1) l+n+\alpha] r_{k} r_{l} P_{n-k} P_{n-l}, \\
n(n+2) P_{n+1}^{2}= & (n+1)^{2} P_{n+1}^{2}-P_{n+1}^{2}, \\
n(n+2) P_{n} P_{n+2}= & \sum_{k=0}^{n-1} \sum_{l=0}^{n+1}[(\alpha-1) k+n-1+\alpha][(\alpha-1) l+n+1+\alpha] \times r_{k} r_{l} P_{n-1-k} P_{n+1-l} .
\end{aligned}
$$

The first equation follows from the fact that the right hand side equals $(n+\alpha) P_{n} \cdot(n+1) P_{n+1}-(n+$ $1+\alpha) P_{n+1} \cdot n P_{n}=\alpha P_{n} P_{n+1}$. Define

$$
\begin{equation*}
J_{n}^{(1)}=\left(\alpha r_{0} P_{n}-P_{n+1}\right) P_{n+1} . \tag{A.2}
\end{equation*}
$$

Then,

$$
\begin{aligned}
& n(n+2)\left[P_{n+1}^{2}-P_{n} P_{n+2}\right] \\
& =\left(\alpha r_{0} P_{n} P_{n+1}^{2}-P_{n+1}^{2}\right)+(n+1)^{2} P_{n+1}^{2}-n(n+2) P_{n} P_{n+2}-\alpha r_{0} P_{n} P_{n+1} \\
& =J_{n}^{(1)}+\sum_{k=0}^{n} \sum_{l=0}^{n}[(\alpha-1) k+n+\alpha][(\alpha-1) l+n+\alpha] r_{k} r_{l} P_{n-k} P_{n-l} \\
& \quad-\sum_{k=0}^{n-1} \sum_{l=0}^{n+1}[(\alpha-1) k+n-1+\alpha][(\alpha-1) l+n+1+\alpha] r_{k} r_{l} P_{n-1-k} P_{n+1-l} \\
& \quad-r_{0} \sum_{j=0}^{n}[(\alpha-1) j+n+\alpha](n+\alpha) r_{j} P_{n-j} P_{n} \\
& \quad+r_{0} \sum_{j=0}^{n-1}[(\alpha-1) j+n-1+\alpha](n+1+\alpha) r_{j} P_{n-1-j} P_{n+1}
\end{aligned}
$$

$$
\begin{aligned}
= & J_{n}^{(1)}+\sum_{k=0}^{n} \sum_{l=1}^{n}[(\alpha-1) k+n+\alpha][(\alpha-1) l+n+\alpha] r_{k} r_{l} P_{n-k} P_{n-l} \\
& -\sum_{k=0}^{n-1} \sum_{l=1}^{n+1}[(\alpha-1) k+n-1+\alpha][(\alpha-1) l+n+1+\alpha] r_{k} r_{l} P_{n-1-k} P_{n+1-l} \\
= & J_{n}^{(1)}+\sum_{k=0}^{n} \sum_{l=0}^{n}[(\alpha-1) k+n+\alpha][(\alpha-1)(l+1)+n+\alpha] r_{k} r_{l+1} P_{n-k} P_{n-1-l} \\
& -\sum_{k=0}^{n} \sum_{l=0}^{n}[(\alpha-1) k+n-1+\alpha][(\alpha-1)(l+1)+n+1+\alpha] r_{k} r_{l+1} P_{n-1-k} P_{n-l} \\
= & J_{n}^{(1)}+\sum_{k=0}^{n} \sum_{l=0}^{n}[\alpha(k+1)+n-k][\alpha(l+2)+n-l-1] r_{k} r_{l+1} P_{n-k} P_{n-1-l} \\
& -\sum_{k=0}^{n} \sum_{l=0}^{n}[\alpha(k+1)+n-1-k][\alpha(l+2)+n-l] r_{k} r_{l+1} P_{n-1-k} P_{n-l} \\
= & J_{n}^{(1)}+J_{n}^{(2)}+J_{n}^{(3)}+J_{n}^{(4)},
\end{aligned}
$$

where $J_{n}^{(2)}, J_{n}^{(3)}$ and $J_{n}^{(4)}$ are defined by

$$
\begin{aligned}
J_{n}^{(2)}= & \alpha^{2} \sum_{k=0}^{n} \sum_{l=0}^{n}(k+1)(l+2) r_{k} r_{l+1}\left[P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right] \\
= & \alpha^{2} \sum_{k \geq l}\left[P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right]\left[(k+1)(l+2) r_{k} r_{l+1}-(l+1)(k+2) r_{l} r_{k+1}\right], \\
J_{n}^{(3)}= & \sum_{k=0}^{n} \sum_{l=0}^{n}\left[(n-k)(n-l-1) P_{n-k} P_{n-1-l}-(n-1-k)(n-l) P_{n-1-k} P_{n-l}\right] r_{k} r_{l+1} \\
= & \sum_{k \geq l}\left[(n-k)(n-l-1) P_{n-k} P_{n-1-l}-(n-1-k)(n-l) P_{n-1-k} P_{n-l}\right]\left(r_{k} r_{l+1}-r_{l} r_{k+1}\right), \\
J_{n}^{(4)}= & \alpha \sum_{k=0}^{n} \sum_{l=0}^{n} r_{k} r_{l+1}[(k+1)(n-l-1)+(n-k)(l+2)] P_{n-k} P_{n-1-l} \\
& -\alpha \sum_{k=0}^{n} \sum_{l=0}^{n} r_{k} r_{l+1}[(k+1)(n-l)+(n-k-1)(l+2)] P_{n-1-k} P_{n-l} .
\end{aligned}
$$

Define function $h(k, l)=(k+1)(n-l)+(n-k-1)(l+2)$, which satisfies $h(k, l)=h(l, k)$. Therefore, $J_{n}^{(4)}$ can be simplified to:

$$
\begin{aligned}
J_{n}^{(4)}= & \left.\alpha \sum_{k=0}^{n} \sum_{l=0}^{n} r_{k} r_{l+1}[(h(k, l))+l-k+1) P_{n-k} P_{n-1-l}-h(k, l) P_{n-1-k} P_{n-l}\right] \\
= & \alpha \sum_{k=0}^{n} \sum_{l=0}^{n} r_{k} r_{l+1} h(k, l)\left(P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right) \\
& +\alpha \sum_{k=0}^{n} \sum_{l=0}^{n} r_{k} r_{l+1}(l-k+1) P_{n-k} P_{n-1-l} \\
= & \alpha \sum_{k \geq l} h(k, l)\left(P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right)\left(r_{k} r_{l+1}-r_{l} r_{k+1}\right)
\end{aligned}
$$

$$
\begin{align*}
& +\alpha \sum_{k=0}^{n} \sum_{l=1}^{n+1} r_{k} r_{l}(l-k) P_{n-k} P_{n-l} \\
= & \alpha \sum_{k \geq l} h(k, l)\left(P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right)\left(r_{k} r_{l+1}-r_{l} r_{k+1}\right)+\alpha \sum_{k=0}^{n} r_{k} r_{0} k P_{n-k} P_{n} \\
\geq & \alpha \sum_{k \geq l} h(k, l)\left(P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right)\left(r_{k} r_{l+1}-r_{l} r_{k+1}\right) . \tag{A.3}
\end{align*}
$$

Then, we prove the log-concavity of $\left\{P_{n}, n \geq 0\right\}$ by induction. For $k=1$, it is the same as (4.3). Now assume $P_{k}^{2} \geq P_{k-1} P_{k+1}$ for all $k \leq n$. To prove $P_{n+1}^{2} \geq P_{n} P_{n+2}$, it suffices to prove:

$$
J_{n}^{(1)}+J_{n}^{(2)}+J_{n}^{(3)}+J_{n}^{(4)} \geq 0 .
$$

In fact, $J_{n}^{(v)} \geq 0$ for all $v \in\{1,2,3,4\}$. Details are as follows.

- $v=1$ : By the assumption of induction, we have $\alpha r_{0}=P_{1} / P_{0} \geq P_{2} / P_{1} \geq P_{n+1} / P_{n}$ and, hence, $J_{n}^{(1)} \geq 0$ due to (A.2).
- $v=2$ : $f \in \mathrm{LC}$ implies that $\left\{(i+1) r_{i}, i \geq 0\right\}$ is also log-concave. Hence,

$$
(k+1)(l+2) r_{k} r_{l+1} \geq(l+1)(k+2) r_{l} r_{k+1}, \quad k \geq l
$$

Furthermore, $P_{n-k} P_{n-1-l} \geq P_{n-1-k} P_{n-l}$ for $k \geq l$, which holds by the assumption of induction. So, $J_{n}^{(2)} \geq 0$.

- $v=3$ : The hypothesis means that $P_{k}$ is log-concave in $k \in\{0,1, \cdots, n+1\}$, implying that $k P_{k}$ is log-concave in $k \in\{0,1, \ldots, n+1\}$. Therefore,

$$
(n-k)(n-l-1) P_{n-k} P_{n-1-l} \geq(n-1-k)(n-l) P_{n-1-k} P_{n-l}, \quad k \geq l .
$$

Obviously, $r_{k} r_{l+1} \geq r_{l} r_{k+1}$ for $k \geq l$. Thus, $J_{n}^{(3)} \geq 0$.

- $v=4$ : By the definition of $h(k, l)$, we have

$$
h(k, l) \geq 0, \forall k \leq n-1 ; \quad h(n, n-1)=0 ; \quad h(n, l)>0, \forall l \leq n-2 .
$$

Applying (A.3), we have

$$
\begin{aligned}
J_{n}^{(4)} \geq \alpha & \sum_{l \leq k \geq n-1} h(k, l)\left(P_{n-k} P_{n-1-l}-P_{n-1-k} P_{n-l}\right)\left(r_{k} r_{l+1}-r_{l} r_{k+1}\right) \\
& +\alpha \sum_{l=0}^{n} h(n, l) P_{0} P_{n-1-l}\left(r_{n} r_{l+1}-r_{l} r_{n+1}\right) \geq 0
\end{aligned}
$$

Based on the above discussion, the log-concavity of $\left\{P_{n}, n \geq 0\right\}$ is proved by induction.
