Aims. The aims of this project were to assess how well the Netflix drama 13 Reasons Why portrayed suicide, in terms of both accuracy and safety, and to discuss the potential effect this could have on viewers.

Background. Psychiatric content within dramatic media can have measurable effects on the population, such as reinforcing stigma around mental illness. Given the show's focus on a character's suicide, the most serious effect here would be suicide contagion.

Guidelines and regulations for the portrayal of suicide in media are in place to protect those who might be vulnerable to suicide contagion.

Method. We formed our own pro-forma of 42 criteria using existing guidelines written for both news and dramatic media. These criteria were formatted into positive and negative pairs; positive being instances of guidelines being followed, negative as guidelines being broken. These were further organised into 7 categories.

Each episode of seasons 1-2 was then assessed against the criteria. Cumulative instances of guidelines being followed or broken were compared within and between seasons. Context of each instance was taken into account by the primary researcher, and we also highlighted instances of exceptional breach of these guidelines.

Result. The results showed an over-all breach of the guidelines, with no significant improvement between the seasons. Some categories of criteria, such as "asking for help" and "mental health", were portrayed well overall. Other categories, such as "blame", performed extremely badly.

The most significant breach was the graphic suicide scene at the end of the first season, which completely disregarded Samaritans' guidelines.

Conclusion. The breaching of guidelines in this show was overwhelming. In terms of severity, although there were some positive themes running through the seasons, there were also worrying instances of guidelines being completely disregarded. This led to the conclusion that the producers of the show did not take their responsibility to young, vulnerable viewers seriously regarding the dangers around portraying suicide.

Suggestions from this study are that more guidelines around suicide are needed specifically for dramatic media, and that existing guidelines should be conflated and have stronger implementation by regulators. This implementation should potentially include overseas providers such as Netflix. Ethically, a significant challenge here is maintaining balance between safety and allowing artistic licence.

Psychiatric liaison referrals: a thematic analysis during peak COVID-19

Aims. With the advent of the COVID-19 Pandemic the NHS long term Plan commitments of January 2019 to improve crisis care

nationwide became all the more pressing. The aim of this study was to thematically investigate what mental health crisis presentations might be diverted from the Emergency department to external crisis hubs in order to reduce the COVID-19 contamination risks.

Method. All referrals made to the Homerton University Hospital (HUH) mental health liaison service were looked at between 1/3/20-11/6/20 (n = 846), coinciding with the first peak of the COVID-19 Pandemic.

Referral data was anonymised and sorted independently into naturally emerging thematic classes by two junior liaison doctors.

Cases that did not clearly fit any of the 14 themes generated were further looked into to determine outcome of referral and discussed to try and match to an appropriate class.

Result. 14 frequent themes for mental health crisis referrals were identified. The distribution of these ranged from most common (suicidality) to neurocognitive presentation and identified shifts in themes over the course of the pandemic peak such as increases of low mood, anxiety and intoxication requiring medical attention over the three month period.

Conclusion. Although themes for presentations may be identified in acute referrals to mental health liaison services it is problematic determining how these may be parsed safely to crisis hubs without risking overlooking cases that may require medical attention. The most common theme that was identified and remained throughout the first wave of the COVID-19 Pandemic was acute suicidal presentation. The remaining themes would require careful consideration around risk thresholds for what a service may wish to accept in devolving the emergency department liaison and balance these against future risks of repeat COVID-19 waves.

Staff survey on using the new clinical risk assessment framework for teams (CRAFT) tool

Aims. Risk assessment and management are crucial elements of clinical practice in mental health. Healthcare Improvement Scotland identified risk management as a key area for change, with risk tools identified as one necessary component. In NHS Greater Glasgow and Clyde (GG&C) the CRAFT tool replaced the Glasgow Risk Screen (GRS) in October 2019. The CRAFT tool is a 2 page document that comprises a broad risk screen, details of historical risk events and prompts for family and carer involvement. The aim of this study was to assess staff attitudes to the CRAFT, 12 months after it had been rolled out. Looking at whether the CRAFT tool is used to inform decision making about risk in clinical settings and if patients were involved in the risk management process.

Method. An electronic staff survey was distributed to all clinical staff within NHS GG&C Mental Health Services. Clinical staff includes the following professional groups: Medical, Nursing, Psychology, Occupational Therapists and Allied Health Professionals. Contact details were accessed via the relevant managers and surveys were sent via secure global address lists. Questions were focused around the following areas: time taken to complete/update/frequency of use/contact and ease of use, role in decision making, patient and carer involvement/knowledge, view on the impact of the CRAFT.
