(Received 4 September 2008)

#### Abstract

This paper aims to lay the foundations for a combinatorial study, via orthogonal functions and intertwining operators, of category $\mathcal{O}$ for the rational Cherednik algebra of type $G(r, p, n)$. As a first application, a self-contained and elementary proof of the analogue for the groups $G(r, p, n)$, with $r>1$, of Gordon's Theorem (previously Haiman's Conjecture) on the diagonal co-invariant ring is given. No restriction is imposed on $p$; the result for $p \neq r$ has been proved by Vale using a technique analogous to Gordon's. Because of the combinatorial application to Haiman's Conjecture, the paper is logically self-contained except for standard facts about complex reflection groups. The main results should be accessible to mathematicians working in algebraic combinatorics who are unfamiliar with the impressive range of ideas used in Gordon's proof of his theorem.

Keywords: complex reflection groups; Catalan numbers; diagonal co-invariant rings; Jack polynomials

## 1. Introduction

The aim of this paper is twofold. First, we introduce intertwining operators for the rational Cherednik algebra (RCA) $\mathbb{H}$ of type $G(r, p, n)$ and carry out sufficient calculation of the relations they satisfy to be useful for a combinatorial study of the representation theory of $\mathbb{H}$. This work forms the basis for the sequels $[\mathbf{1 5}, \mathbf{1 6}]$, where we study the combinatorics of the ordinary co-invariant ring and begin the combinatorial study of the lattice of submodules of each standard module for the rational Cherednik algebra. Our goal is the construction of canonical bases for the standard modules $M(V)$ and their composition factors, including the irreducible quotients $L(V)$.

Second, we use the intertwining operators to give a new and self-contained (modulo standard facts about complex reflection groups) proof of the analogue of Gordon's Theorem $[\mathbf{1 2}, \mathbf{2 5}]$ on the diagonal co-invariant ring for $G(r, p, n)$. The proof here works only when $r>1$ but does not place any restriction on $p$; Vale [25] establishes the result for $p \neq r$. We use neither the KZ functor and cyclotomic Hecke algebras (as in $[\mathbf{1 2}, \mathbf{2 5}]$ ) nor degeneration from the double affine Hecke algebra (as in [5]) as there is no double affine Hecke algebra available for the groups $G(r, p, n)$ with $r>2$, although we found
the ideas of those papers inspirational. The existence of this paper also owes much to the foundational papers $[\mathbf{9}, \mathbf{1 1}]$.

One of our goals being self-containment, we begin in $\S 2$ with definitions and a sketch of the proof of the Poincaré-Birkhoff-Witt Theorem for rational Cherednik algebras. In § 3 we explain the formalism that connects the rational Cherednik algebra to quotients of the diagonal co-invariant ring of the type conjectured by Haiman [17]. In $\S 4$ we specialize to the case of the groups $G(r, p, n)$ and review the construction given in [9] of an important commutative subalgebra of the rational Cherednik algebra $\mathbb{H}$. We study the intertwining operators and their basic properties in $\S 5$ and study their action on a particular basis of the polynomial representation in $\S 6$. We determine the submodule structure of the polynomial representation of $G(r, p, n)$ in the cases that we will use for the study of the diagonal co-invariant ring in $\S 7$. The results of $\S 7$ are similar to, but more detailed than, those contained in [6]. The extra detail is crucial for the material of $\S 8$, where we study the $\mathbb{H}$-modules fulfilling the requirements of $\S 3$ and relevant to the diagonal co-invariant ring.

## 2. Definitions and the Poincaré-Birkhoff-Witt Theorem

Let $V$ be a finite-dimensional vector space over a field $k$, and let $W \subseteq \mathrm{GL}(V)$ be a finite subgroup. Let $T V$ be the tensor algebra of $V$ and let $k W$ be the group algebra of $W$ over $k$, with basis $t_{w}$ for $w \in W$ and multiplication $t_{w} t_{v}=t_{w v}$. The semi-direct product $T V \rtimes W$ is $T V \otimes_{k} k W$ with multiplication

$$
\begin{equation*}
\left(f \otimes t_{w}\right)\left(g \otimes t_{v}\right)=f(w g) \otimes t_{w v} \quad \text { for } f, g \in T V \text { and } w, v \in W \tag{2.1}
\end{equation*}
$$

From now on we will drop the tensor signs when it will not cause confusion. Fix a collection of skew-symmetric forms indexed by the elements of $W$ :

$$
\begin{equation*}
\langle\cdot, \cdot\rangle_{w}: V \times V \rightarrow k \quad \text { for } w \in W \tag{2.2}
\end{equation*}
$$

The Drinfel' $d$-Hecke algebra $\mathbb{H}$ corresponding to these data is the quotient of the algebra $T V \otimes_{k} k W$ by the relations

$$
\begin{equation*}
x y-y x=\sum_{w \in W}\langle x, y\rangle_{w} t_{w} \quad \text { for } x, y \in V \tag{2.3}
\end{equation*}
$$

Now let $\mathfrak{h}$ be a finite-dimensional $k$-vector space. A reflection is an element $s \in \operatorname{GL}(\mathfrak{h})$ such that $\operatorname{codim}(\operatorname{fix}(s))=1$. A reflection group is a finite subgroup $W \subseteq \operatorname{GL}(\mathfrak{h})$ that is generated by the set of reflections it contains. Assume now that $W$ is a reflection group, let $T$ be the set of reflections it contains, and put $V=\mathfrak{h}^{*} \oplus \mathfrak{h}$. Write $\langle x, y\rangle=x(y)$ for $x \in \mathfrak{h}^{*}$ and $y \in \mathfrak{h}$. For each $s \in T$, fix $\alpha_{s} \in \mathfrak{h}^{*}$ and $\alpha_{s}^{\vee} \in \mathfrak{h}$ with

$$
\begin{equation*}
s x=x-\left\langle x, \alpha_{s}^{\vee}\right\rangle \alpha_{s} \quad \text { for all } x \in \mathfrak{h}^{*}, \tag{2.4}
\end{equation*}
$$

and define skew symmetric bilinear forms $\langle\cdot, \cdot\rangle_{s}$ on $V$ by the requirements

$$
\langle x, y\rangle_{s}= \begin{cases}0 & \text { if } x, y \in \mathfrak{h} \text { or } x, y \in \mathfrak{h}^{*},  \tag{2.5}\\ c_{s}\left\langle\alpha_{s}, y\right\rangle\left\langle x, \alpha_{s}^{\vee}\right\rangle & \text { if } x \in \mathfrak{h}^{*} \text { and } y \in \mathfrak{h},\end{cases}
$$

where $c_{s} \in k$ satisfy $c_{w s w^{-1}}=c_{s}$ for all $s \in T$ and $w \in W$. It is straightforward to check that $\langle\cdot, \cdot\rangle_{s}$ does not depend on the choice of $\alpha_{s}$ and $\alpha_{s}^{\vee}$ satisfying (2.4). We extend the pairing $\langle\cdot, \cdot\rangle$ between $\mathfrak{h}$ and $\mathfrak{h}^{*}$ to a symplectic form on $V$ by requiring that $\mathfrak{h}$ and $\mathfrak{h}^{*}$ be isotropic.

The rational Cherednik algebra corresponding to a reflection group $W$ is the quotient of the semi-direct product $T V \rtimes W$ by the relations

$$
\begin{equation*}
y x-x y=\kappa\langle x, y\rangle-\sum_{s \in T}\langle x, y\rangle_{s} t_{s} \quad \text { for } x, y \in V \tag{2.6}
\end{equation*}
$$

where $\kappa \in k$. It is thus a special case of the Drinfel'd-Hecke algebra. Note that by the definitions of $\langle\cdot, \cdot\rangle$ and $\langle\cdot, \cdot\rangle_{s}$, we have

$$
\begin{equation*}
y x-x y=0 \quad \text { if } x, y \in \mathfrak{h} \text { or } x, y \in \mathfrak{h}^{*} \tag{2.7}
\end{equation*}
$$

and hence there are canonical maps $S(\mathfrak{h}) \rightarrow \mathbb{H}$ and $S\left(\mathfrak{h}^{*}\right) \rightarrow \mathbb{H}$.
Now assume that $\mathbb{H}$ is the Drinfel ${ }^{\prime}$ d-Hecke algebra associated to a collection $\langle\cdot, \cdot\rangle_{w}$ of skew symmetric forms as above. We say that the PBW Theorem holds for $\mathbb{H}$ if, for any basis $x_{1}, \ldots, x_{n}$ of $V$, the collection $\left\{x_{i_{1}} x_{i_{2}} \cdots x_{i_{p}} t_{w} \mid 1 \leqslant i_{1} \leqslant i_{2} \leqslant \cdots \leqslant i_{p} \leqslant n\right.$, w $\in$ $W\}$ is a basis for $\mathbb{H}$. The following theorem was stated in $[\mathbf{8}]$ and many proofs have now appeared (see, for example, $[\mathbf{2}, \mathbf{1 0}, \mathbf{1 1}, \mathbf{1 8}, \mathbf{2 3}]$ ). Our proof has the virtue of working in arbitrary characteristic; more importantly, it is conceptually extremely simple.

Theorem 2.1 (the Poincaré-Birkhoff-Witt Theorem for Drinfel'd-Hecke algebras). The Poincaré-Birkhoff-Witt (PBW) Theorem holds for $\mathbb{H}$ if and only if the following two conditions hold:
(a) $\langle v x, v y\rangle_{v w v^{-1}}=\langle x, y\rangle_{w}$ for all $x, y \in V$ and $v, w \in W$, and
(b) $\langle x, y\rangle_{w}(w z-z)+\langle y, z\rangle_{w}(w x-x)+\langle z, x\rangle_{w}(w y-y)=0$ for all $x, y, z \in V$ and $w \in W$.

Proof. First assume that the PBW Theorem holds for $\mathbb{H}$. Let $x, y \in V$ and $v \in W$. Equating coefficients on both sides of

$$
\begin{equation*}
\sum_{w \in W}\langle v x, v y\rangle_{w} t_{w}=[v x, v y]=t_{v}[x, y] t_{v}^{-1}=\sum_{w \in W}\langle x, y\rangle_{w} t_{v w v^{-1}} \tag{2.8}
\end{equation*}
$$

implies that (a) holds. Let $x, y, z \in V$. By the Jacobi identity,

$$
\begin{aligned}
0 & =[[x, y], z]+[[y, z], x]+[[z, x], y] \\
& =\left[\sum_{w \in W}\langle x, y\rangle_{w} t_{w}, z\right]+\left[\sum_{w \in W}\langle y, z\rangle_{w} t_{w}, x\right]+\left[\sum_{w \in W}\langle z, x\rangle_{w} t_{w}, y\right] \\
& =\sum_{w \in W}\left(\langle x, y\rangle_{w}(w z-z)+\langle y, z\rangle_{w}(w x-x)+\langle z, x\rangle_{w}(w y-y)\right) t_{w}
\end{aligned}
$$

Now, equating coefficients of $t_{w}$ on both sides implies that (b) holds.

Conversely, assume that (a) and (b) hold. The defining relations for $\mathbb{H}$ evidently imply that, given any basis $x_{1}, x_{2}, \ldots, x_{n}$ of $V$, the set $\left\{x_{i_{1}} x_{i_{2}} \cdots x_{i_{p}} t_{w} \mid 1 \leqslant i_{1} \leqslant i_{2} \leqslant \cdots \leqslant\right.$ $\left.i_{p} \leqslant n, w \in W\right\}$ spans $\mathbb{H}$. We will show that these elements are also linearly independent by mimicking the standard proof of the PBW Theorem for universal enveloping algebras of Lie algebras: we construct the module that ought to be the left regular representation of $\mathbb{H}$. Let $M$ be the vector space with basis consisting of the words $\left\{x_{i_{1}} x_{i_{2}} \cdots x_{i_{p}} t_{w}\right.$ | $\left.1 \leqslant i_{1} \leqslant i_{2} \leqslant \cdots \leqslant i_{p} \leqslant n, w \in W\right\}$. Define operators $l_{x}$ and $l_{v}$ on $M$ for $x \in V$ and $v \in W$ inductively as follows:

$$
\begin{equation*}
l_{x} \cdot t_{w}=x t_{w}, \quad l_{v} \cdot t_{w}=t_{v w} \tag{2.9}
\end{equation*}
$$

and, for $p \geqslant 1$,

$$
l_{x_{i}} \cdot x_{i_{1}} \cdots x_{i_{p}} t_{w}= \begin{cases}x_{i} x_{i_{1}} \cdots x_{i_{p}} t_{w} & \text { if } i \leqslant i_{1}  \tag{2.10}\\ l_{x_{i_{1}}} \cdot l_{x_{i}} \cdot x_{i_{2}} \cdots x_{i_{p}} t_{w}+\sum_{v \in W}\left\langle x_{i}, x_{i_{1}}\right\rangle_{v} l_{v} \cdot x_{i_{2}} \cdots x_{i_{p}} t_{w} & \text { if } i>i_{1}\end{cases}
$$

and

$$
\begin{equation*}
l_{v} \cdot x_{i_{1}} \cdots x_{i_{p}} t_{w}=l_{v x_{i_{1}}} \cdot l_{v} \cdot x_{i_{2}} \cdots x_{i_{p}} t_{w} \tag{2.11}
\end{equation*}
$$

A straightforward but lengthy calculation shows that these operators satisfy the defining relations for $\mathbb{H}$. It follows that $M$ is an $\mathbb{H}$-module, with $x$ acting by $l_{x}$ and $t_{w}$ acting by $l_{w}$. Suppose that there is a relation in $\mathbb{H}$ of the form

$$
\sum_{\substack{w \in W, \leqslant i_{1} \leqslant \cdots \leqslant i_{p} \leqslant n}} a_{i_{1} \cdots i_{p}, w} x_{i_{1}} \cdots x_{i_{p}} t_{w}=0
$$

with $a_{i_{1} \cdots i_{p}, w} \in k$. Applying both sides of this relation to the element $1=t_{1} \in M$ implies that all the coefficients $a_{i_{1} \cdots i_{p}, w}$ are zero, and the proof is complete.

Corollary 2.2. Let $\mathbb{H}$ be the rational Cherednik algebra corresponding to the reflection group $W$. Then the multiplication map $S\left(\mathfrak{h}^{*}\right) \otimes_{k} S(\mathfrak{h}) \otimes_{k} k W \rightarrow \mathbb{H}$ is an isomorphism.

Proof. The result follows from the previous theorem once we check that conditions (a) and (b) of that theorem hold. Condition (a) is straightforward to verify. Condition (b) holds trivially for $w \notin T$. If $s \in T$ and $z \in \operatorname{fix}_{V}(s)$, then the definitions (2.4) and (2.5) imply $\langle z, x\rangle_{s}=0$ for all $x \in V$. Therefore, the radical of $\langle\cdot, \cdot\rangle_{s}$ has codimension at most 2 . If $\langle\cdot, \cdot\rangle_{s} \neq 0$, then we may choose $x, y \in V$ with $\langle x, y\rangle_{s}=1$, and for any $z \in V$ we have

$$
\begin{equation*}
z=\langle x, z\rangle_{s} y-\langle y, z\rangle_{s} x+f \quad \text { with } f \in \operatorname{fix}_{V}(s) \tag{2.12}
\end{equation*}
$$

Applying $s-1$ to both sides and rearranging terms shows that the identity (b) holds for $x, y$ and arbitrary $z$. In general, identity (b) holds trivially if every two of $x, y, z$ are linearly dependent modulo the radical of $\langle\cdot, \cdot\rangle_{s}$, so we are reduced to the case just treated.

There is an important filtration of $\mathbb{H}$ defined by

$$
\begin{equation*}
\mathbb{H}^{\leqslant m}=k-\operatorname{span}\left\{x_{i_{1}} \cdots x_{i_{l}} t_{w} \mid l \leqslant m, w \in W \text { and } x_{i_{j}} \in \mathfrak{h}^{*} \oplus \mathfrak{h}\right\} . \tag{2.13}
\end{equation*}
$$

By the PBW Theorem for $\mathbb{H}$, the associated graded algebra of $\mathbb{H}$ with respect to this filtration is the semidirect product $S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right) \rtimes W$.

Our next proposition is a fundamental computation. It expresses some commutators in $\mathbb{H}$ as linear combinations of derivatives and divided differences of elements of $S\left(\mathfrak{h}^{*}\right)$ and $S(\mathfrak{h})$. For $y \in \mathfrak{h}$, we write $\partial_{y}$ for the derivation of $S\left(\mathfrak{h}^{*}\right)$ determined by

$$
\begin{equation*}
\partial_{y}(x)=\langle x, y\rangle \quad \text { for } x \in \mathfrak{h}^{*} \tag{2.14}
\end{equation*}
$$

and we define a derivation $\partial_{x}$ of $S(\mathfrak{h})$ analogously.
Proposition 2.3. Let $y \in \mathfrak{h}$ and $f \in S\left(\mathfrak{h}^{*}\right)$. Then

$$
\begin{equation*}
y f-f y=\kappa \partial_{y} f-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{f-s f}{\alpha_{s}} t_{s} \tag{2.15}
\end{equation*}
$$

Similarly, for $x \in \mathfrak{h}^{*}$ and $g \in S(\mathfrak{h})$, we have

$$
\begin{equation*}
g x-x g=\kappa \partial_{x} g-\sum_{s \in T} c_{s}\left\langle x, \alpha_{s}^{\vee}\right\rangle t_{s} \frac{g-s^{-1} g}{\alpha_{s}^{\vee}} \tag{2.16}
\end{equation*}
$$

Remark 2.4. Note the placement of $t_{s}$ in the second formula. In practice, it is sometimes convenient to rewrite it as

$$
\begin{equation*}
g x-x g=\kappa \partial_{x} g-\sum_{s \in T} c_{s}\left\langle x, \alpha_{s}^{\vee}\right\rangle \frac{s g-g}{s \alpha_{s}^{\vee}} t_{s} \tag{2.17}
\end{equation*}
$$

Proof. Observe that if $f=x \in \mathfrak{h}^{*}$, the first formula to be proved is

$$
y x-x y=\kappa\langle x, y\rangle-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{x-s x}{\alpha_{s}} t_{s}
$$

and the right-hand side may be rewritten as

$$
\kappa\langle x, y\rangle-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle\left\langle x, \alpha_{s}^{\vee}\right\rangle t_{s}
$$

so that the formula to be proved is one of the defining relations for $\mathbb{H}$. We proceed by induction on the degree of $f$. Assume we have proved the result for $h \in S^{d}\left(\mathfrak{h}^{*}\right)$ and all $d \leqslant m$. For $f, g \in S^{\leqslant m}\left(\mathfrak{h}^{*}\right)$ and $y \in \mathfrak{h}$ we have

$$
\begin{aligned}
{[y, f g] } & =[y, f] g+f[y, g] \\
& =\left(\kappa \partial_{y}(f)-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{f-s f}{\alpha_{s}} t_{s}\right) g+f\left(\kappa \partial_{y}(g)-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{g-s g}{\alpha_{s}} t_{s}\right) \\
& =\kappa\left(\partial_{y}(f) g+f \partial_{y}(g)\right)-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle\left(\frac{f-s f}{\alpha_{s}} s g+f \frac{g-s g}{\alpha_{s}}\right) t_{s} \\
& =\kappa \partial_{y}(f g)-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{f g-s(f g)}{\alpha_{s}} t_{s},
\end{aligned}
$$

by using the inductive hypothesis in the second equality and the Leibniz rule for $\partial_{y}$ and a skew Leibniz rule for the divided differences in the fourth equality. This proves the first commutator formula, and the proof of the second one is exactly analogous.

Let $V$ be a $k W$-module and define an $S(\mathfrak{h}) \rtimes k W$ action on $V$ by

$$
\begin{equation*}
f \cdot v=f(0) v \quad \text { and } \quad t_{w} \cdot v=w v \quad \text { for } w \in W, f \in S(\mathfrak{h}) \tag{2.18}
\end{equation*}
$$

The standard module corresponding to $V$ is

$$
\begin{equation*}
M(V)=\operatorname{Ind}_{S(\mathfrak{h}) \rtimes k W}^{\mathbb{H}} V . \tag{2.19}
\end{equation*}
$$

The PBW Theorem shows that $\mathbb{H}$ is a free $S(\mathfrak{h}) \rtimes k W$-module, so that the additive functor $V \mapsto M(V)$ is exact and, as a $k$-vector space,

$$
\begin{equation*}
M(V) \simeq S\left(\mathfrak{h}^{*}\right) \otimes_{k} V \tag{2.20}
\end{equation*}
$$

In particular, when $V=\mathbf{1}$ is the trivial $k W$-module, we obtain from Proposition 2.3 that

$$
\begin{equation*}
M(\mathbf{1}) \simeq S\left(\mathfrak{h}^{*}\right) \quad \text { with } y \cdot f=\kappa \partial_{y} f-\sum_{s \in T} c_{s}\left\langle\alpha_{s}, y\right\rangle \frac{f-s f}{\alpha_{s}} \tag{2.21}
\end{equation*}
$$

for $y \in \mathfrak{h}$ and $f \in S\left(\mathfrak{h}^{*}\right)$. These are the famous Dunkl operators. From our point of view, the fact that they commute is a consequence of the PBW Theorem, though it is possible to prove the commutativity independently (see, for example, $[\mathbf{9}]$ ) and then use it to establish the PBW Theorem.

The definition (2.19) implies that the module $M(V)$ has the following universal property: given an $\mathbb{H}$-module $M$ and a $W$-stable subspace $U \subseteq M$ such that $V \cong U$ as $W$ modules and $y \cdot U=0$ for all $y \in \mathfrak{h}$, there is a unique $\mathbb{H}$-module homomorphism $M(V) \rightarrow M$ which restricts to the given isomorphism $V \cong U$.

Define the element $h \in \mathbb{H}$ by

$$
\begin{equation*}
h=\sum_{i=1}^{n} x_{i} y_{i}+\sum_{s \in T} c_{s}\left(1-t_{s}\right) \tag{2.22}
\end{equation*}
$$

where $x_{i}$ is a basis of $\mathfrak{h}^{*}$ and $y_{i}$ is the dual basis of $\mathfrak{h}$. Calculations using the defining relations for $\mathbb{H}$ show that

$$
\begin{equation*}
[h, x]=\kappa x, \quad[h, y]=-\kappa y \quad \text { and } \quad\left[h, t_{w}\right]=0 \tag{2.23}
\end{equation*}
$$

for $x \in \mathfrak{h}^{*}, y \in \mathfrak{h}$ and $w \in W$. Thus, if $\kappa=1$ and $V$ is an irreducible $W$-module, the $h$ action on the Verma module $M(V)$ is given by

$$
\begin{equation*}
h \cdot f v=\left(\operatorname{deg}(f)+c_{V}\right) f v \quad \text { for } f \in S\left(\mathfrak{h}^{*}\right) \text { homogeneous and } v \in V \tag{2.24}
\end{equation*}
$$

where $c_{V}$ is the scalar by which $\sum_{s \in T} c_{s}\left(1-t_{s}\right)$ acts on $V$.
When $\kappa=1$ the formula (2.24) implies that each standard module $M(V)$ has a unique irreducible quotient $L(V)$. This paper is primarily concerned with the module $L(\mathbf{1})$ in those cases related to diagonal co-invariants, but the techniques developed will be applied in the sequel, $[\mathbf{1 6}]$, to obtain detailed information on the submodule structure of $M(V)$ for more general representations $V$.

## 3. Diagonal co-invariants

We now describe a situation in which we can relate $L(\mathbf{1})$ to the diagonal co-invariant ring

$$
\begin{equation*}
R=S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right) / I, \quad \text { where } I=S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right)_{+}^{W} S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right) \tag{3.1}
\end{equation*}
$$

Recall the filtration (2.13) of $\mathbb{H}$ with $\mathfrak{h}^{*} \oplus \mathfrak{h}$ in degree 1 and $\mathbb{C} W$ in degree 0 . By (2.6) and the PBW Theorem, the associated graded algebra of $\mathbb{H}$ with respect to this filtration is $S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right) \rtimes W$. It is this fact that was used in [12] (and that we will use in Theorem 3.2) to make the connection to diagonal co-invariants.

In this section, we assume that we are working with an irreducible complex reflection group $W$ of rank $n$. When $A$ is a graded vector space, we write $A_{i}$ for the $i$ th graded piece.

Lemma 3.1. Assume that there is an irreducible module $V$ of dimension $n$ such that there is an exact sequence $M(V) \rightarrow M(\mathbf{1}) \rightarrow L(\mathbf{1}) \rightarrow 0$ with $L(\mathbf{1})$ finite dimensional. Then the Koszul complex

$$
0 \rightarrow S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{n} V \rightarrow \cdots \rightarrow S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{1} V \rightarrow S\left(\mathfrak{h}^{*}\right) \rightarrow L(\mathbf{1}) \rightarrow 0
$$

is exact and the maps are maps of $\mathbb{H}$-modules. The graded $W$-character of $L(\mathbf{1})$ is

$$
\sum_{i \geqslant 0} \operatorname{tr}\left(w, L(\mathbf{1})_{i}\right) t^{i}=\frac{\operatorname{det}\left(1-t^{k} w_{V}\right)}{\operatorname{det}\left(1-t w_{\mathfrak{h}^{*}}\right)}
$$

where the image of $V$ in $M(\mathbf{1})$ lies in degree $k$ and $w_{V}$ and $w_{\mathfrak{h}^{*}}$ denote $w$ regarded as an endomorphism of $V$ and $\mathfrak{h}^{*}$, respectively.

Proof. Since $V$ is $n$-dimensional and $L(\mathbf{1})$ is finite dimensional, the image of $V$ under the map $M(V) \rightarrow M(\mathbf{1})$ is spanned by a regular sequence. Hence, the Koszul complex is exact. As a vector space $M\left(\Lambda^{i} V\right) \cong S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{i} V$ and, using this identification, the vector spaces in the Koszul complex are $\mathbb{H}$-modules. By assumption, the first map is a map of $\mathbb{H}$-modules; its kernel is therefore an $\mathbb{H}$-submodule. The kernel is generated as an $S\left(\mathfrak{h}^{*}\right)$-submodule by $\Lambda^{2} V$ and it follows that the second map in the Koszul complex is a map of $\mathbb{H}$-modules. One proves in the same way, by induction on $i$, that the $i$ th map in the Koszul complex is a map of $\mathbb{H}$-modules. That the graded $W$-character of $L(\mathbf{1})$ is as asserted is a routine calculation using the Koszul resolution.

If $V$ is an irreducible $W$-module of dimension $l$, its exponents are the integers $e_{1} \leqslant$ $e_{2} \leqslant \cdots \leqslant e_{l}$ defined by the equation

$$
\sum_{i \geqslant 0}\left[\left(S\left(\mathfrak{h}^{*}\right) / J\right)_{i}: V\right] t^{i}=\sum_{i=1}^{r} t^{e_{i}}
$$

where $J$ is the ideal generated by the positive degree elements of the invariant ring $S\left(\mathfrak{h}^{*}\right)^{W}$ and $\left(S\left(\mathfrak{h}^{*}\right) / J\right)_{i}$ denotes the $i$ th graded piece. Since $W$ is a complex reflection
group, the invariant ring $S\left(\mathfrak{h}^{*}\right)^{W}$ is generated by $n$ algebraically independent polynomials $f_{1}, \ldots, f_{n}$ with degrees $d_{1} \leqslant d_{2} \leqslant \cdots \leqslant d_{n}$.

An irreducible representation $V$ is free if $\left(S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{*} V^{*}\right)^{W}$ is a free exterior algebra over $S\left(\mathfrak{h}^{*}\right)^{W}$. By [21, Theorem 3.1], $V$ is free if $e_{1}+\cdots+e_{l}$ is the (unique) exponent of $\Lambda^{l} V$. By the proof of [21, Theorem 3.3], the Galois conjugates of the reflection representation $\mathfrak{h}$ are all free. In Lemma 8.1 we will give some other examples of free representations of the group $G(r, p, n)$ that will be relevant to the diagonal co-invariant ring.

Theorem 3.2. With assumptions as in Lemma 3.1, assume moreover that $V$ is free and the image of $V$ in $M(\mathbf{1})$ lies in degree $k$ for an integer $k$ such that the multisets $\left\{k-e_{i}\right\}_{i=1}^{n}$ and $\left\{d_{i}\right\}_{i=1}^{n}$ are equal. Then there is a unique occurrence of $\Lambda^{n} V$ in $L(\mathbf{1})$, lying in degree $e_{1}+\cdots+e_{n}$. Let $v \in L(\mathbf{1})$ span this occurrence of $\Lambda^{n} V$, and filter $L(\mathbf{1})$ by

$$
L(\mathbf{1})^{\leqslant i}=\mathbb{H}^{\leqslant i} \cdot v
$$

Then the map gr $\mathbb{H} \rightarrow \operatorname{gr} L(\mathbf{1})$ restricts to a surjection $R \rightarrow \operatorname{gr} L(\mathbf{1})$, which has $W$-character given by Lemma 3.1. Finally, the image in $\operatorname{gr} L(\mathbf{1})$ of $S\left(\mathfrak{h}^{*}\right)$ is isomorphic to the ordinary co-invariant ring $S\left(\mathfrak{h}^{*}\right) / J$.

Proof. In light of Lemma 3.1, the occurrences of $\Lambda^{n} V$ in $L(\mathbf{1})$ are given by the formula

$$
\sum\left[L(1)_{j}: \Lambda^{n} V\right] t^{j}=\sum(-1)^{i}\left[S\left(\mathfrak{h}^{*}\right)_{j-i k} \otimes \Lambda^{i} V: \Lambda^{n} V\right] t^{j}
$$

and we compute the occurrences of $\Lambda^{n} V$ in $S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{*} V$ by use of the $W$-equivariant isomorphism $\Lambda^{i} V \otimes \Lambda^{n} V^{*} \cong \Lambda^{n-i} V^{*}$. Thus,

$$
\left[S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{i} V: \Lambda^{n} V\right]=\operatorname{dim}_{\mathbb{C}}\left(S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{n-i} V^{*}\right)^{W}
$$

On the other hand, the assumption that $\left(S\left(\mathfrak{h}^{*}\right) \otimes \Lambda^{*} V^{*}\right)^{W}$ is a free exterior algebra over $S\left(\mathfrak{h}^{*}\right)^{W}$ implies that

$$
\sum \operatorname{dim}_{\mathbb{C}}\left(S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{i} V^{*}\right)^{W} q^{i} t^{j}=\prod_{i=1}^{n} \frac{1+q t^{e_{i}}}{1-t^{d_{i}}}
$$

Thus,

$$
\begin{aligned}
\sum\left[L(1)_{j}: \Lambda^{n} V\right] t^{j} & =\sum(-1)^{i}\left[S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{i} V: \Lambda^{n} V\right] t^{j+i k} \\
& =\sum(-1)^{i} \operatorname{dim}_{\mathbb{C}}\left(S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{n-i} V^{*}\right)^{W} t^{j+i k} \\
& =\sum(-1)^{n-i} \operatorname{dim}_{\mathbb{C}}\left(S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{i} V^{*}\right)^{W} t^{j+(n-i) k} \\
& =(-1)^{n} t^{n k}\left[\sum \operatorname{dim}_{\mathbb{C}}\left(S\left(\mathfrak{h}^{*}\right)_{j} \otimes \Lambda^{i} V^{*}\right)^{W} q^{i} t^{j}\right]_{q=-t^{-k}} \\
& =(-1)^{n} t^{n k} \prod_{i=1}^{n} \frac{1-t^{e_{i}-k}}{1-t^{d_{i}}} \\
& =t^{e_{1}+\cdots+e_{n}} \prod_{i=1}^{n} \frac{1-t^{k-e_{i}}}{1-t^{d_{i}}} \\
& =t^{e_{1}+\cdots+e_{n}} .
\end{aligned}
$$

Upon filtering $L(\mathbf{1})$ and taking the corresponding associated graded module as in the statement of the theorem, it follows that there is a unique copy of $\Lambda^{n} V$ in $\operatorname{gr} L(\mathbf{1})$. Since $L(\mathbf{1})$ is an irreducible $\mathbb{H}$-module, the map

$$
\left.\begin{array}{rl}
\operatorname{gr} \mathbb{H} & \rightarrow \operatorname{gr} L(\mathbf{1}),  \tag{3.2}\\
f & \rightarrow f \cdot v,
\end{array}\right\}
$$

is surjective. By the PBW-theorem, $\operatorname{gr} \mathbb{H}=S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right) \otimes \mathbb{C} W$, and the above map remains surjective upon restriction to $S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right)$. Since $v$ is the unique occurrence of $\Lambda^{n} V$ in $\operatorname{gr} L(\mathbf{1})$, we have $S\left(\mathfrak{h}^{*} \oplus \mathfrak{h}\right)_{+}^{W} \cdot v=0$ and it follows that $\operatorname{gr} L(\mathbf{1})$ is a quotient of the diagonal co-invariant ring.

Let $N=|T|$ be the number of reflections in $W$; it is a standard fact that the socle of the ordinary co-invariant ring $S\left(\mathfrak{h}^{*}\right) / J$ is spanned by $\prod_{s \in T} \alpha_{s}$ and hence lies in degree $N$. The equation $N=d_{1}-1+d_{2}-1+\cdots+d_{n}-1$ is also well known. By Lemma 3.1 and the hypotheses of the theorem, the top degree piece of $L(\mathbf{1})$ lies in degree

$$
n(k-1)=e_{1}+\cdots+e_{n}+d_{1}+\cdots+d_{n}-n=e_{1}+\cdots+e_{n}+N
$$

Since $L(\mathbf{1})$ is irreducible the map

$$
\left.\begin{array}{rl}
S\left(\mathfrak{h}^{*}\right) \otimes S(\mathfrak{h}) & \rightarrow \operatorname{gr} L(\mathbf{1}),  \tag{3.3}\\
f & \rightarrow f \cdot v,
\end{array}\right\}
$$

is surjective. It follows that the socle of $S\left(\mathfrak{h}^{*}\right) / J$ is not in the kernel of the induced map, and hence the co-invariant ring is the image of $S\left(\mathfrak{h}^{*}\right)$.

If in addition to the hypotheses of Lemma 3.1 we assume that $V^{*}$ is free, then an analogous calculation shows that

$$
\begin{equation*}
\sum \operatorname{dim}_{\mathbb{C}} L(\mathbf{1})_{i}^{W} t^{i}=\prod_{i=1}^{n} \frac{1-t^{k+e_{i}^{\prime}}}{1-t^{d_{i}}} \tag{3.4}
\end{equation*}
$$

where $e_{1}^{\prime}, \ldots, e_{n}^{\prime}$ are the exponents of $V^{*}$. This fact establishes a connection to the conjectural $t$-analogue of the $W$-Catalan number discovered by Bessis and Reiner [4]: if, with the assumptions of Lemma 3.1, $W$ is a complex reflection group that can be generated by $n$ reflections, $k=h+1$, where $h=d_{n}$ is the largest degree (i.e. Coxeter number), and $V=\mathfrak{h}^{*}$, then

$$
\begin{equation*}
\sum \operatorname{dim}_{\mathbb{C}} L(\mathbf{1})_{i}^{W} t^{i}=\prod_{i=1}^{n} \frac{1-t^{h+d_{i}}}{1-t^{d_{i}}} \tag{3.5}
\end{equation*}
$$

It does not seem unreasonable to expect that, for most of the exceptional complex reflection groups $W$ and appropriate values of the parameters in the definition of $\mathbb{H}$, the module $L(\mathbf{1})$ gives rise to both a nice quotient of the diagonal co-invariant ring and a $t$-analogue of the $W$-Catalan number.

## 4. The rational Cherednik algebra for $G(r, p, n)$

Let $G(r, 1, n)$ be the group of $n \times n$ monomial matrices whose entries are $r$ th roots of 1 . Let

$$
\begin{equation*}
\zeta=\mathrm{e}^{2 \pi \mathrm{i} / r} \quad \text { and } \quad \zeta_{i}^{l}=\operatorname{diag}\left(1, \ldots, \zeta^{l}, \ldots, 1\right) \text { for } 1 \leqslant i \leqslant n \tag{4.1}
\end{equation*}
$$

Let

$$
\begin{equation*}
s_{i}=s_{i, i+1}, \quad \text { where } s_{i j}=(i j) \text { for } 1 \leqslant i<j \leqslant n \tag{4.2}
\end{equation*}
$$

is the transposition interchanging $i$ and $j$. There are $r$ conjugacy classes of reflections in $G(r, 1, n)$ :
(a) the reflections of order 2 ,

$$
\begin{equation*}
\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l} \quad \text { for } 1 \leqslant i<j \leqslant n, 0 \leqslant l \leqslant r-1 \tag{4.3}
\end{equation*}
$$

and
(b) the remaining $r-1$ classes, consisting of diagonal matrices

$$
\begin{equation*}
\zeta_{i}^{l} \quad \text { for } 1 \leqslant i \leqslant n, 1 \leqslant l \leqslant r-1 \tag{4.4}
\end{equation*}
$$

where $\zeta_{i}^{l}$ and $\zeta_{j}^{k}$ are conjugate if and only if $k=l$.
Let

$$
y_{i}=(0, \ldots, 1, \ldots, 0)^{t} \quad \text { and } \quad x_{i}=(0, \ldots, 1, \ldots, 0)
$$

have 1 s in the $i$ th position and 0 s elsewhere, so that $y_{1}, \ldots, y_{n}$ is the standard basis of $\mathfrak{h}=\mathbb{C}^{n}$ and $x_{1}, \ldots, x_{n}$ is the dual basis in $\mathfrak{h}^{*}$. If

$$
\alpha_{s}=\zeta^{-l-1} x_{i}, \quad \alpha_{s}^{\vee}=\left(\zeta^{l+1}-\zeta\right) y_{i} \quad \text { for } s=\zeta_{i}^{l}
$$

and

$$
\alpha_{s}=x_{i}-\zeta^{l} x_{j}, \quad \alpha_{s}^{\vee}=y_{i}-\zeta^{-l} y_{j} \quad \text { for } s=\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}
$$

then, with $\langle\cdot, \cdot\rangle$ denoting the canonical pairing between $\mathfrak{h}^{*}$ and $\mathfrak{h}$,

$$
s x=x-\left\langle x, \alpha_{s}^{\vee}\right\rangle \alpha_{s} \quad \text { and } \quad s^{-1}(y)=y-\left\langle\alpha_{s}, y\right\rangle \alpha_{s}^{\vee},
$$

for $s \in T, x \in \mathfrak{h}^{*}$ and $y \in \mathfrak{h}$. We relabel the parameters defining $\mathbb{H}$ by letting

$$
\begin{equation*}
c_{0}=c_{s_{1}} \quad \text { and } \quad c_{i}=c_{\zeta_{1}^{i}} \text { for } 1 \leqslant i \leqslant r-1 . \tag{4.5}
\end{equation*}
$$

Proposition 4.1. The rational Cherednik algebra for $W=G(r, 1, n)$ with parameters $\kappa, c_{0}, c_{1}, \ldots, c_{r-1}$, is the algebra generated by $\mathbb{C}\left[x_{1}, \ldots, x_{n}\right], \mathbb{C}\left[y_{1}, \ldots, y_{n}\right]$ and $t_{w}$ for $w \in W$ with relations

$$
t_{w} t_{v}=t_{w v}, \quad t_{w} x=(w x) t_{w} \quad \text { and } \quad t_{w} y=(w y) t_{w}
$$

for $w, v \in W, x \in \mathfrak{h}^{*}$ and $y \in \mathfrak{h}$,

$$
\begin{equation*}
y_{i} x_{j}=x_{j} y_{i}+c_{0} \sum_{l=0}^{r-1} \zeta^{-l} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} \tag{4.6}
\end{equation*}
$$

for $1 \leqslant i \neq j \leqslant n$, and

$$
\begin{equation*}
y_{i} x_{i}=x_{i} y_{i}+\kappa-\sum_{l=1}^{r-1} c_{l}\left(1-\zeta^{-l}\right) t_{\zeta_{i}^{l}}-c_{0} \sum_{j \neq i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} \tag{4.7}
\end{equation*}
$$

for $1 \leqslant i \leqslant n$.
Proof. This is just a matter of rewriting formula (2.6) using our $G(r, 1, n)$-specific notation. For $1 \leqslant i<j \leqslant n$,

$$
\begin{aligned}
y_{i} x_{j}= & x_{j} y_{i}+\kappa\left\langle x_{j}, y_{i}\right\rangle \\
& \quad-c_{0} \sum_{1 \leqslant k<m \leqslant n} \sum_{l=0}^{r-1}\left\langle x_{k}-\zeta^{l} x_{m}, y_{i}\right\rangle\left\langle x_{j}, y_{k}-\zeta^{-l} y_{m}\right\rangle t_{\zeta_{k}^{l} s_{k m} \zeta_{k}^{-l}} \\
& -\sum_{k=1}^{n} \sum_{l=1}^{r-1} c_{l}\left\langle\zeta^{-l-1} x_{k}, y_{i}\right\rangle\left\langle x_{j},\left(\zeta^{l+1}-\zeta\right) y_{k}\right\rangle t_{\zeta_{k}^{l}} \\
= & x_{j} y_{i}+\kappa \cdot 0-c_{0} \sum_{l=0}^{r-1}\left(-\zeta^{-l}\right) t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}-0 \\
= & x_{j} y_{i}+c_{0} \sum_{l=0}^{r-1} \zeta^{-l} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}
\end{aligned}
$$

The calculation for $1 \leqslant j<i \leqslant n$ is similar. For $i=j$,

$$
\begin{aligned}
& y_{i} x_{i}= x_{i} y_{i}+\kappa\left\langle x_{i}, y_{i}\right\rangle \\
&-c_{0} \sum_{1 \leqslant k<m \leqslant n} \sum_{l=0}^{r-1}\left\langle x_{k}-\zeta^{l} x_{m}, y_{i}\right\rangle\left\langle x_{i}, y_{k}-\zeta^{-l} y_{m}\right\rangle t_{\zeta_{k}^{l} s_{k m} \zeta_{k}^{-l}} \\
&-\sum_{k=1}^{n} \sum_{l=1}^{r-1} c_{l}\left\langle\zeta^{-l-1} x_{k}, y_{i}\right\rangle\left\langle x_{i},\left(\zeta^{l+1}-\zeta\right) y_{k}\right\rangle t_{\zeta_{k}^{l}} \\
&= x_{i} y_{i}+\kappa-c_{0} \sum_{1 \leqslant i<m \leqslant n} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i m} \zeta_{i}^{-l}} \\
& \quad-c_{0} \sum_{1 \leqslant k<i \leqslant n} \sum_{l=0}^{r-1} t_{\zeta_{k}^{l} s_{i k} \zeta_{k}^{-l}}-\sum_{l=1}^{r-1} c_{l}\left(1-\zeta^{-l}\right) t_{\zeta_{i}^{l}}
\end{aligned}
$$

Most of the equations that occur later on are simpler in terms of a certain reparametrization. For $j \in \mathbb{Z}$ define

$$
\begin{equation*}
d_{j}=\sum_{l=1}^{r-1} \zeta^{l j} c_{l} \tag{4.8}
\end{equation*}
$$

It follows that $d_{0}+d_{1}+\cdots+d_{r-1}=0$ and that, for $1 \leqslant l \leqslant r-1$,

$$
\begin{equation*}
c_{l}=\frac{1}{r} \sum_{j=0}^{r-1} \zeta^{-l j} d_{j} \tag{4.9}
\end{equation*}
$$

The defining relation (4.7) becomes

$$
\begin{equation*}
y_{i} x_{i}=x_{i} y_{i}+\kappa-\sum_{j=0}^{r-1}\left(d_{j}-d_{j-1}\right) \epsilon_{i j}-c_{0} \sum_{j \neq i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} \tag{4.10}
\end{equation*}
$$

where, for $0 \leqslant j \leqslant r-1$, the primitive idempotents for the cyclic reflection subgroup of $W$ generated by $\zeta_{i}$ are

$$
\begin{equation*}
\epsilon_{i j}=\frac{1}{r} \sum_{l=0}^{r-1} \zeta^{-l j} t_{\zeta_{i}^{l}} \tag{4.11}
\end{equation*}
$$

The complex reflection group $G(r, p, n)$ is the subgroup of $G(r, 1, n)$ consisting of those matrices so that the product of the non-zero entries is an $r / p$ th root of 1 . The reflections in $G(r, p, n)$ are
(a) $\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}$ for $1 \leqslant i<j \leqslant n$ and $0 \leqslant l \leqslant r-1$, and
(b) $\zeta_{i}^{l p}$ for $1 \leqslant i \leqslant n$ and $0 \leqslant l \leqslant r / p-1$.

When $n \geqslant 3$, the rational Cherednik algebra for $G(r, p, n)$ is the subalgebra of the rational Cherednik algebra $\mathbb{H}$ for $G(r, 1, n)$ with parameters

$$
c_{l}=0 \quad \text { if } p \text { does not divide } l
$$

generated by $\mathbb{C}\left[x_{1}, \ldots, x_{n}\right], \mathbb{C}\left[y_{1}, \ldots, y_{n}\right]$ and $\mathbb{C} G(r, p, n)$. Although this is not strictly speaking true for $n=2$, our results on the diagonal co-invariant ring still hold in that case except when $p=r=2$.

Although not strictly necessary for the results of this paper, it seems worthwhile to mention here that when $c_{l}=0$ for $l$ not divisible by $p$ there is a cyclic group of automorphisms, generated by

$$
\begin{equation*}
x \mapsto x, \quad y \mapsto y, \quad s_{i} \mapsto s_{i}, \quad t_{\zeta_{j}} \mapsto \zeta^{r / p} t_{\zeta_{j}} \tag{4.12}
\end{equation*}
$$

for $x \in \mathfrak{h}^{*}, y \in \mathfrak{h}, 1 \leqslant i \leqslant n-1$, and $1 \leqslant j \leqslant n$, of the rational Cherednik algebra $\mathbb{H}$ for $G(r, 1, n)$ so that the rational Cherednik algebra for $G(r, p, n)$ is the fixed subalgebra. The version of Clifford theory given in [22] therefore applies to deduce representation theoretic results for the $G(r, p, n)$ RCA from those for the $G(r, 1, n)$ RCA.

From now on, $p$ dividing $r$ will be fixed and we work with the rational Cherednik algebra $\mathbb{H}$ for $G(r, p, n)$. Note that, with the parameters $c_{l}=0$ for $l$ not divisible by $p$, we have $d_{j}=d_{k}$ if $j=k \bmod r / p$.

Our first goal is identify a certain commutative subalgebra $\mathfrak{t}$ of $\mathbb{H}$. Later on we will use the subalgebra $\mathfrak{t}$ to diagonalize the standard module $M(\mathbf{1})$ (as in [ $\mathbf{9}]$ ), a result which is generalized in the paper $[\mathbf{1 6}]$. For $1 \leqslant i \leqslant n$ define

$$
\begin{equation*}
z_{i}=y_{i} x_{i}+c_{0} \phi_{i}, \quad \text { where } \phi_{i}=\sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} \tag{4.13}
\end{equation*}
$$

The following proposition is proved in [9].

Proposition 4.2. The elements $z_{1}, \ldots, z_{n}$ of $\mathbb{H}$ are pairwise commutative:

$$
z_{i} z_{j}=z_{j} z_{i} \quad \text { for } 1 \leqslant i, j \leqslant n
$$

Proof. We begin by computing

$$
\begin{aligned}
{\left[y_{i} x_{i}, y_{j} x_{j}\right] } & =y_{i} x_{i} y_{j} x_{j}-y_{j} x_{j} y_{i} x_{i} \\
& =y_{i}\left(x_{i} y_{j}-y_{j} x_{i}\right) x_{j}+y_{j}\left(y_{i} x_{j}-x_{j} y_{i}\right) x_{i} \\
& =-y_{i}\left(c_{0} \sum_{l=0}^{r-1} \zeta^{-l} t_{\zeta_{j}^{l} s_{i j} \zeta_{j}^{-l}}\right) x_{j}+y_{j}\left(c_{0} \sum_{l=0}^{r-1} \zeta^{-l} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right) x_{i} \\
& =-y_{i} x_{i}\left(c_{0} \sum_{l=0}^{r-1} t_{\zeta_{j}^{l} s_{i j} \zeta_{j}^{-l}}\right)+\left(c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right) y_{i} x_{i} \\
& =-\left[y_{i} x_{i}, c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right] .
\end{aligned}
$$

Thus,

$$
\begin{equation*}
\left[y_{i} x_{i}, y_{j} x_{j}+c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right]=0 \tag{4.14}
\end{equation*}
$$

Let

$$
\psi_{i}=\phi_{1}+\cdots+\phi_{i}=\sum_{1 \leqslant j<k \leqslant i} \sum_{l=0}^{r-1} t_{\zeta_{k}^{l} s_{j k} \zeta_{k}^{-l}}
$$

Then $\psi_{i}$ is a conjugacy class sum and therefore a central element of the group algebra of $G(r, 1, i)$. It follows that $\psi_{i}$ commutes with $\psi_{1}, \ldots, \psi_{i}$. Therefore, $\psi_{1}, \psi_{2}, \ldots, \psi_{n}$ are pairwise commutative and hence $\phi_{1}, \ldots, \phi_{n}$ are pairwise commutative.

Using the commutativity of the $\phi_{i}$, the commutator formula (4.14), and the fact that $y_{j} x_{j}$ commutes with $\phi_{i}$ for $i<j$, we assume that $i<j$ and compute

$$
\begin{aligned}
{\left[z_{i}, z_{j}\right] } & =\left[y_{i} x_{i}+c_{0} \phi_{i}, y_{j} x_{j}+c_{0} \phi_{j}\right] \\
& =\left[y_{i} x_{i}, y_{j} x_{j}+c_{0} \phi_{j}\right] \\
& =\left[y_{i} x_{i}, y_{j} x_{j}+c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}+c_{0} \sum_{1 \leqslant k \neq i<j} \sum_{l=0}^{r-1} t_{\zeta_{j}^{l} s_{j k} \zeta_{j}^{-l}}\right] \\
& =0 .
\end{aligned}
$$

As observed in [7, Proposition 1.1], the relations in the following lemma imply that the subalgebra of $\mathbb{H}$ generated by $G(r, p, n)$ and $z_{1}, \ldots, z_{n}$ is isomorphic to the graded Hecke algebra for $G(r, p, n)$ defined in [23, §5] (the elements $z_{1}, \ldots, z_{n}$ are algebraically independent over $\mathbb{C}$ by the PBW Theorem).

Proposition 4.3. Working in the rational Cherednik algebra $\mathbb{H}$ for $G(r, 1, n)$, we have

$$
\begin{array}{ll}
z_{i} t_{\zeta_{j}}=t_{\zeta_{j}} z_{i} & \text { for } 1 \leqslant i, j \leqslant n, \\
z_{i} t_{s_{i}}=t_{s_{i}} z_{i+1}-c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} \zeta_{i+1}-1} & \text { for } 1 \leqslant i \leqslant n, \\
z_{i} t_{s_{j}}=t_{s_{j}} z_{i} & \text { for } 1 \leqslant i \leqslant n \text { and } j \neq i, i+1 . \tag{4.17}
\end{array}
$$

Proof. First we observe that the elements $t_{\zeta_{i}}$ and $\phi_{j}$ commute for all $1 \leqslant i, j \leqslant n$. This is clear if $i>j$; if $i=j$, then

$$
t_{\zeta_{j}} \phi_{j} t_{\zeta_{j}}^{-1}=t_{\zeta_{j}} \sum_{1 \leqslant k<j} \sum_{l=0}^{r-1} t_{\zeta_{j}^{l} s_{j k} \zeta_{j}^{-l}} t_{\zeta_{j}}^{-1}=\sum_{1 \leqslant k<j} \sum_{l=0}^{r-1} t_{\zeta_{j}^{l+1} s_{j k} \zeta_{j}^{-l-1}}=\phi_{j} ;
$$

a similar computation handles the case $i<j$. Then (4.15) follows from

$$
t_{\zeta_{i}} y_{i} x_{i}=\zeta y_{i} t_{\zeta_{i}} x_{i}=\zeta \zeta^{-1} y_{i} x_{i} t_{\zeta_{i}}=y_{i} x_{i} t_{\zeta_{i}} \quad \text { for } 1 \leqslant i, j \leqslant n .
$$

For (4.16),

$$
\begin{aligned}
z_{i} t_{s_{i}} & =\left(y_{i} x_{i}+c_{0} \sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right) t_{s_{i}} \\
& =t_{s_{i}}\left(y_{i+1} x_{i+1}+c_{0} \sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1, j} \zeta_{i+1}^{-l}}\right) \\
& =t_{s_{i}} z_{i+1}-t_{s_{i}} c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1, i} \zeta_{i+1}^{-l}} \\
& =t_{s_{i}} z_{i+1}-c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} \zeta_{i+1}^{-l}}^{-l} .
\end{aligned}
$$

Finally, we observe that if $j \neq i, i+1$, then $t_{s_{j}}$ commutes with $\phi_{i}$ and with $y_{i} x_{i}$, and hence with $z_{i}=y_{i} x_{i}+c_{0} \phi_{i}$.

Let

$$
\begin{equation*}
\mathfrak{t}=\mathbb{C}\left[z_{1}, \ldots, z_{n}, t_{\zeta_{1} \zeta_{2}^{-1}}, \ldots, t_{\zeta_{n-1} \zeta_{n}^{-1}}, t_{\zeta_{1}^{p}}, \ldots, t_{\zeta_{n}^{p}}\right] \tag{4.18}
\end{equation*}
$$

By Proposition 4.2 and Lemma 4.3, the subalgebra $\mathfrak{t}$ is a commutative subalgebra of $\mathbb{H}$. Our goal is to use $\mathfrak{t}$ in much the same way as a Cartan subalgebra of a semisimple Lie algebra.

## 5. Intertwiners

In this section we will prove many formulae using elements of $G(r, 1, n)$ that are not in $G(r, p, n)$; since the rational Cherednik algebra for $G(r, p, n)$ is a subalgebra of a specialization of that for $G(r, 1, n)$, these formulae have consequences in the rational Cherednik algebra for $G(r, p, n)$.

The following lemma is a generalization of (4.16) and (4.17). Let

$$
\begin{equation*}
\pi_{i}=\sum_{l=0}^{r-1} t_{\zeta_{i}^{l} \zeta_{i+1}^{-l}} \tag{5.1}
\end{equation*}
$$

Lemma 5.1. Let $f$ be a rational function of $z_{1}, \ldots, z_{n}$. Then

$$
\begin{equation*}
t_{s_{i}} f=\left(s_{i} f\right) t_{s_{i}}-c_{0} \pi_{i} \frac{f-s_{i} f}{z_{i}-z_{i+1}} \quad \text { for } 1 \leqslant i \leqslant n-1 \tag{5.2}
\end{equation*}
$$

Proof. Observe that if $f$ is $z_{i}, z_{i+1}$ or $z_{j}$ for $j \neq i, i+1$, then the relation to be proved follows from (4.16) and (4.17). Assume that the relation (5.2) is true for rational functions $f$ and $g$. Then it is evidently true for $f+g$ and $a f$ for all $a \in \mathbb{C}$, and we compute

$$
\begin{aligned}
t_{s_{i}} f g & =\left(t_{s_{i}} f-\left(s_{i} f\right) t_{s_{i}}\right) g+\left(s_{i} f\right)\left(t_{s_{i}} g-\left(s_{i} g\right) t_{s_{i}}\right)+\left(s_{i} f g\right) t_{s_{i}} \\
& =\left(-c_{0} \pi_{i} \frac{f-s_{i} f}{z_{i}-z_{i+1}}\right) g+\left(s_{i} f\right)\left(-c_{0} \pi_{i} \frac{g-s_{i} g}{z_{i}-z_{i+1}}\right)+\left(s_{i} f g\right) t_{s_{i}} \\
& =\left(s_{i} f g\right) t_{s_{i}}-c_{0} \pi_{i} \frac{f g-s_{i} f g}{z_{i}-z_{i+1}}
\end{aligned}
$$

so (5.2) is true for $f g$. Assuming it is true for the rational function $f$, we compute

$$
\begin{aligned}
\left(t_{s_{i}} 1 / f-\left(1 / s_{i} f\right) t_{s_{i}}\right) f\left(s_{i} f\right) & =t_{s_{i}} s_{i} f-1 / s_{i} f\left(\left(s_{i} f\right) t_{s_{i}}-c_{0} \pi_{i} \frac{f-s_{i} f}{z_{i}-z_{i+1}}\right) s_{i} f \\
& =c_{0} \pi_{i} \frac{f-s_{i} f}{z_{i}-z_{i+1}}
\end{aligned}
$$

and dividing by $f\left(s_{i} f\right)$ proves that the relation holds for $1 / f$. Since it holds for $z_{1}, \ldots, z_{n}$, it is true for all rational functions in $z_{1}, \ldots, z_{n}$.

The intertwining operators $\sigma_{i}$ for $1 \leqslant i \leqslant n-1$ are

$$
\begin{equation*}
\sigma_{i}=t_{s_{i}}+\frac{c_{0}}{z_{i}-z_{i+1}} \pi_{i}, \quad \text { where } \pi_{i}=\sum_{l=0}^{r-1} t_{\zeta_{i}^{l} \zeta_{i+1}^{-l}}, \tag{5.3}
\end{equation*}
$$

and we define intertwining operators $\Phi$ and $\Psi$ by

$$
\begin{equation*}
\Phi=x_{n} t_{s_{n-1} s_{n-2} \cdots s_{1}} \quad \text { and } \quad \Psi=y_{1} t_{s_{1} s_{2} \ldots s_{n-1}} \tag{5.4}
\end{equation*}
$$

The intertwiner $\Phi$ was first defined in $[\mathbf{1 9}, \S 4]$, where it is used for the symmetric group case. The other intertwiners were defined for the first time in the author's thesis [14], where some of the results that follow were also recorded.

The intertwiner $\sigma_{i}$ is well defined when $\pi_{i}=0$ or $z_{i}-z_{i+1} \neq 0$. The intertwiners are important because, as Lemma 5.3 shows, they permute the $z_{i} \mathrm{~s}$ from (4.13). Our first task is to compute the squares $\sigma_{i}^{2}$ of the intertwiners and the products $\Phi \Psi$ and $\Psi \Phi$. Since these compositions all lie in $\mathfrak{t}$, this calculation is useful for deciding when the intertwiners applied to a t -eigenvector (or generalized eigenvector) are non-zero.

## Lemma 5.2.

(a) For $1 \leqslant i \leqslant n-1$,

$$
\sigma_{i}^{2}=1-\left(\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)^{2}
$$

(b)

$$
\Psi \Phi=z_{1} \quad \text { and } \quad \Phi \Psi=z_{n}-\kappa+\sum_{j=0}^{r-1}\left(d_{j}-d_{j-1}\right) \epsilon_{n j}
$$

Proof. Using Lemma 5.1,

$$
\begin{aligned}
\sigma_{i}^{2}= & \left(t_{s_{i}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)\left(t_{s_{i}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right) \\
= & 1+t_{s_{i}} \frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}} t_{s_{i}}+\left(\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)^{2} \\
= & 1+\frac{c_{0} \pi_{i}}{z_{i+1}-z_{i}} t_{s_{i}}-\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\left(\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}-\frac{c_{0} \pi_{i}}{z_{i+1}-z_{i}}\right) \\
& +\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}} t_{s_{i}}+\left(\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)^{2} \\
= & 1-\left(\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)^{2} .
\end{aligned}
$$

This proves (a), and (b) follows from the definition (5.4) and the relation (4.10).

We define a symmetric group action on $\mathfrak{t}$ by letting $S_{n}$ simultaneously permute $z_{1}, z_{2}, \ldots, z_{n}$ and $t_{\zeta_{1}}, \ldots, t_{\zeta_{n}}$. We also define an automorphism $\phi$ of $\mathfrak{t}$ by

$$
\begin{equation*}
\phi\left(t_{\zeta_{i}}\right)=t_{\zeta_{i+1}} \quad \text { for } 1 \leqslant i \leqslant n-1, \quad \phi\left(t_{\zeta_{n}}\right)=\zeta^{-1} t_{\zeta_{1}} \tag{5.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\phi\left(z_{i}\right)=z_{i+1} \text { for } 1 \leqslant i \leqslant n-1 \quad \text { and } \quad \phi\left(z_{n}\right)=z_{1}+\kappa-\sum_{j=0}^{r-1}\left(d_{j-1}-d_{j-2}\right) \epsilon_{1 j} \tag{5.6}
\end{equation*}
$$

where, as in (4.11), $\epsilon_{1 j}$ are the primitive idempotents for the cyclic reflection subgroup generated by $\zeta_{1}$. There are corresponding operators on the space of homomorphisms $\operatorname{Hom}_{\mathbb{C}-\operatorname{alg}}(\mathfrak{t}, \mathbb{C})$. Identify such an algebra homomorphism $\alpha$ with the sequence $\left(\alpha\left(z_{1}\right), \ldots, \alpha\left(z_{n}\right), \alpha\left(\zeta_{1}\right), \ldots, \alpha\left(\zeta_{n}\right)\right)$. Then $S_{n}$ acts by permutations, and the operators $\phi$ and $\psi$ are as follows:

$$
\begin{align*}
& \phi \cdot\left(\alpha_{1}, \ldots, \alpha_{n}, \zeta^{\beta_{1}}, \ldots, \zeta^{\beta_{n}}\right) \\
&=\left(\alpha_{2}, \ldots, \alpha_{n}, \alpha_{1}+\kappa-d_{\beta_{1}-1}+d_{\beta_{1}-2}, \zeta^{\beta_{2}}, \ldots, \zeta^{\beta_{n}}, \zeta^{\beta_{1}-1}\right) \tag{5.7}
\end{align*}
$$

Let $\psi=\phi^{-1}$, so that

$$
\begin{align*}
& \psi \cdot\left(\alpha_{1}, \ldots, \alpha_{n}, \zeta^{\beta_{1}}, \ldots, \zeta^{\beta_{n}}\right) \\
& \quad=\left(\alpha_{n}-\kappa+d_{\beta_{n}}-d_{\beta_{n}-1}, \alpha_{1}, \ldots, \alpha_{n-1}, \zeta^{\beta_{n}+1}, \zeta^{\beta_{1}}, \ldots, \zeta^{\beta_{n-1}}\right) \tag{5.8}
\end{align*}
$$

## Lemma 5.3.

(a) For $1 \leqslant i \leqslant n-1$ and $f \in \mathfrak{t}$,

$$
\sigma_{i} f=\left(s_{i} \cdot f\right) \sigma_{i}
$$

(b) For $f \in \mathfrak{t}$,

$$
f \Phi=\Phi(\phi \cdot f) \quad \text { and } \quad f \Psi=\Psi\left(\phi^{-1} \cdot f\right)
$$

Proof. The commutation relation (4.16) for $z_{i}$ and $t_{s_{i}}$ gives

$$
\begin{aligned}
z_{i} \sigma_{i} & =z_{i}\left(t_{s_{i}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right) \\
& =t_{s_{i}} z_{i+1}-c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} \zeta_{i+1}^{-l}}+\frac{c_{0} \pi_{i} z_{i}}{z_{i}-z_{i+1}} \\
& =\sigma_{i} z_{i+1}-\frac{c_{0} \pi_{i} z_{i+1}}{z_{i}-z_{i+1}}-c_{0} \pi_{i}+\frac{c_{0} \pi_{i} z_{i}}{z_{i}-z_{i+1}} \\
& =\sigma_{i} z_{i+1}
\end{aligned}
$$

The proof that $z_{i+1} \sigma_{i}=\sigma_{i} z_{i}$ is exactly analogous, and the fact that $\sigma_{i}$ and $z_{j}$ commute if $j \neq i, i+1$ is obvious.

Using the relation $t_{\zeta_{i}} \pi_{i}=\pi_{i} t_{\zeta_{i+1}}$,

$$
t_{\zeta_{i}} \sigma_{i}=t_{\zeta_{i}}\left(t_{s_{i}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}}\right)=t_{s_{i}} t_{\zeta_{i+1}}+\frac{c_{0} \pi_{i}}{z_{i}-z_{i+1}} t_{\zeta_{i+1}}=\sigma_{i} t_{\zeta_{i+1}}
$$

The proof that $t_{\zeta_{i+1}} \sigma_{i}=\sigma_{i} t_{\zeta_{i}}$ is the same, and the fact that $\sigma_{i}$ and $t_{\zeta_{j}}$ commute if $j \neq i, i+1$ is obvious. This proves (a).

Using the commutation formula (4.10) for $y_{n}$ and $x_{n}$,

$$
\begin{aligned}
y_{n} x_{n} \Phi & =\left(x_{n} y_{n}+\kappa-\sum_{j=0}^{r-1}\left(d_{j}-d_{j-1}\right) \epsilon_{n j}-c_{0} \phi_{n}\right) x_{n} t_{s_{n-1}} \cdots t_{s_{1}} \\
& =\Phi y_{1} x_{1}+\kappa \Phi-\Phi \sum_{j=0}^{r-1}\left(d_{j}-d_{j-1}\right) \epsilon_{1, j+1}-c_{0} \phi_{n} \Phi
\end{aligned}
$$

Hence,

$$
z_{n} \Phi=\left(y_{n} x_{n}+c_{0} \phi_{n}\right) \Phi=\Phi\left(z_{1}+\kappa-\sum_{j=0}^{r-1}\left(d_{j-1}-d_{j-2}\right) \epsilon_{1 j}\right)
$$

Let $1 \leqslant i<n$. Since

$$
\begin{aligned}
y_{i} x_{i} \Phi & =y_{i} x_{i} x_{n} t_{s_{n-1} \cdots s_{1}} \\
& =\left(x_{n} y_{i}+c_{0} \sum_{l=0}^{r-1} \zeta^{-l} t_{\zeta_{i}^{l} s_{i n} \zeta_{i}^{-l}}\right) x_{i} t_{s_{n-1} \cdots s_{1}} \\
& =\Phi y_{i+1} x_{i+1}+\Phi c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1,1} \zeta_{i+1}^{-l}}
\end{aligned}
$$

and

$$
\begin{aligned}
\phi_{i} \Phi & =\sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} x_{n} t_{s_{n-1} \cdots s_{1}} \\
& =x_{n} t_{s_{n-1} \cdots s_{1}} \sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1, j+1} \zeta_{i+1}^{-l}} \\
& =\Phi\left(\phi_{i+1}-\sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1,1} \zeta_{i+1}^{-l}}\right),
\end{aligned}
$$

it follows that

$$
\begin{aligned}
z_{i} \Phi & =\left(y_{i} x_{i}+c_{0} \phi_{i}\right) \Phi \\
& =\Phi y_{i+1} x_{i+1}+\Phi c_{0} \sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1,1} \zeta_{i+1}^{-l}}+\Phi c_{0}\left(\phi_{i+1}-\sum_{l=0}^{r-1} t_{\zeta_{i+1}^{l} s_{i+1,1} \zeta_{i+1}^{-l}}\right) \\
& =\Phi z_{i+1} .
\end{aligned}
$$

Finally,

$$
t_{\zeta_{i}} \Phi=t_{\zeta_{i}} x_{n} t_{s_{n-1} \cdots s_{1}}=x_{n} t_{s_{n-1} \cdots s_{1}} t_{\zeta_{i+1}}=\Phi t_{\zeta_{i+1}}
$$

and

$$
t_{\zeta_{n}} \Phi=t_{\zeta_{n}} x_{n} t_{s_{n-1} \cdots s_{1}}=x_{n} t_{s_{n-1} \cdots s_{1}} \zeta^{-1} t_{\zeta_{1}}=\Phi\left(\zeta^{-1} t_{\zeta_{1}}\right)
$$

for $1 \leqslant i<n$. This proves the formula involving $\Phi$. The formula for $\Psi$ follows from that for $\Phi$ by using the relations in part (b) of Lemma 5.2.

## 6. An eigenbasis of $M(1)$

Let $\mathbb{C}\left[x_{1}, x_{2}, \ldots, x_{n}\right]=M(\mathbf{1})$ be the polynomial representation of $\mathbb{H}$. We will show that, for generic choices of the parameters $\kappa$ and $c_{i}$, the ring $\mathbb{C}\left[x_{1}, \ldots, x_{n}\right]$ has an $t$-eigenbasis indexed by the set $\mathbb{Z}_{\geqslant 0}^{n}$ and we will describe how the intertwining operators act on this basis.
For $\mu \in \mathbb{Z}_{\geqslant 0}^{n}$, let $w_{\mu}$ be the maximal length permutation such that $w_{\mu} \cdot \mu=\mu_{-}, \quad$ where $\mu_{-}$is the non-decreasing (anti-partition) rearrangement of $\mu$.

We write $\mu_{+}$for the partition rearrangement of $\mu$, and define a partial order on $\mathbb{Z}_{\geqslant 0}^{n}$ by

$$
\begin{equation*}
\lambda<\mu \quad \Longleftrightarrow \quad \lambda_{+}<_{d} \mu_{+} \text {or } \lambda_{+}=\mu_{+} \text {and } w_{\lambda}<w_{\mu} \tag{6.2}
\end{equation*}
$$

where we use the Bruhat order on $S_{n}$, and $<_{d}$ denotes dominance order on $\mathbb{Z}_{\geqslant 0}^{n}$, given by

$$
\begin{equation*}
\lambda \leqslant_{d} \mu \quad \text { if } \mu-\lambda \in \sum_{i=1}^{n-1} \mathbb{Z}_{\geqslant 0}\left(\epsilon_{i}-\epsilon_{i+1}\right) . \tag{6.3}
\end{equation*}
$$

If $\mu_{i}>\mu_{i+1}$, then

$$
\begin{equation*}
\mu>s_{i} \cdot \mu+k\left(\epsilon_{i}-\epsilon_{i+1}\right) \quad \text { for } 0 \leqslant k<\mu_{i}-\mu_{i+1} . \tag{6.4}
\end{equation*}
$$

The next theorem is the analogue of [20, Theorem 2.6] in our setting. It shows that the $z_{i}$ s are upper triangular as operators on $\mathbb{C}\left[x_{1}, \ldots, x_{n}\right]$ with respect to the order on $\mathbb{Z}_{\geqslant 0}^{n}$ defined in (6.2). Equivalent results are proved [9] by reduction to the symmetric group case. The proof we give below is generalized to the modules $M(V)$ for all irreducible $\mathbb{C} W$-modules $V$ in [16].

## Theorem 6.1.

(a) The actions of $t_{\zeta_{i}}^{p}, t_{\zeta_{i}^{-1} \zeta_{i+1}}$, and $z_{i}$ on $M(\mathbf{1})$ are given by

$$
t_{\zeta_{i}}^{p} \cdot x^{\mu}=\zeta^{-p \mu_{i}} x^{\mu}, \quad t_{\zeta_{i}^{-1} \zeta_{i+1}} \cdot x^{\mu}=\zeta^{\mu_{i}-\mu_{i+1}} x^{\mu}
$$

and, with $d_{j}$ as in (4.8),

$$
z_{i} \cdot x^{\mu}=\left(\kappa\left(\mu_{i}+1\right)-\left(d_{0}-d_{-\mu_{i}-1}\right)-r\left(w_{\mu}(i)-1\right) c_{0}\right) x^{\mu}+\sum_{\nu<\mu} c_{\nu} x^{\nu} .
$$

(b) Assuming that the parameters are generic, so $k=\mathbb{C}\left(\kappa, c_{0}, d_{1}, \ldots, d_{r / p-1}\right)$, for each $\mu \in \mathbb{Z}_{\geqslant 0}^{n}$ there exists a unique $\mathfrak{t}$-eigenvector $f_{\mu} \in M(\mathbf{1})$ such that

$$
f_{\mu, T}=x^{\mu}+\text { lower terms. }
$$

The $\mathfrak{t}$-eigenvalue of $f_{\mu}$ is determined by the formulae in part (a).

Proof. The statements about the action of $t_{\zeta_{i}^{p}}$ and $t_{\zeta_{i} \zeta_{i+1}^{-1}}$ follow from the commutation relation in the definition of the rational Cherednik algebra and the definition of the representation $M(\mathbf{1})$. Using the commutation formula in Proposition 2.3 for $f \in \mathbb{C}\left[x_{1}, \ldots, x_{n}\right]$ and $y \in \mathfrak{h}$ and the geometric series formula to evaluate the divided differences, we obtain the following formula for the action of $y_{i} x_{i}$ on $x^{\mu}$ :

$$
\begin{aligned}
& y_{i} \cdot x^{\mu+\epsilon_{i}}= \kappa\left(\mu_{i}+1\right) x^{\mu}-c_{0} \sum_{1 \leqslant j<k \leqslant n} \sum_{l=0}^{r-1}\left\langle x_{j}-\zeta^{l} x_{k}, y_{i}\right\rangle \frac{x^{\mu+\epsilon_{i}}-\zeta_{j}^{l} s_{j k} \zeta_{j}^{-l} x^{\mu+\epsilon_{i}}}{x_{j}-\zeta^{l} x_{k}} \\
&-\sum_{1 \leqslant j \leqslant n} \sum_{l=1}^{r / p-1} c_{l p}\left\langle x_{j}, y_{i}\right\rangle \frac{x^{\mu+\epsilon_{i}}-\zeta_{j}^{l p} x^{\mu+\epsilon_{i}}}{x_{j}} \\
&= \kappa\left(\mu_{i}+1\right) x^{\mu}-c_{0} \sum_{j \neq i} \sum_{l=0}^{r-1} \frac{x^{\mu+\epsilon_{i}}-\zeta_{i}^{l} s_{i j} \zeta_{\zeta}^{-l} x^{\mu+\epsilon_{i}}}{x_{i}-\zeta^{l} x_{j}} \\
&-\sum_{l=1}^{r / p-1} c_{l p}\left(1-\zeta^{-l p\left(\mu_{i}+1\right)}\right) x^{\mu} \\
&=\left(\kappa\left(\mu_{i}+1\right)-\sum_{l=1}^{r / p-1} c_{l p}\left(1-\zeta^{-l p\left(\mu_{i}+1\right)}\right)\right) x^{\mu} \\
&-c_{0} \sum_{\substack{j \neq i, \mu_{i} \geqslant \mu_{j}}}\left(x^{\mu}+\zeta^{l} x^{\mu+\left(\epsilon_{j}-\epsilon_{i}\right)}+\cdots+\zeta^{l\left(\mu_{i}-\mu_{j}\right)} x^{s_{i j} \mu}\right) \\
&+c_{0} \sum_{\substack{j \neq i,}}^{\mu_{j}>\mu_{i}} \sum_{k=1}^{\mu_{j}-\mu_{i}-1} \zeta^{-l k} x^{\mu+k\left(\epsilon_{i}-\epsilon_{j}\right)} .
\end{aligned}
$$

Using this equation and (6.4) to identify lower terms,

$$
\begin{aligned}
z_{i} \cdot x^{\mu} & =\left(y_{i} x_{i}+c_{0} \sum_{1 \leqslant j<i} \sum_{0 \leqslant l \leqslant r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}}\right) x^{\mu} \\
& =y_{i} \cdot x^{\mu+\epsilon_{i}}+c_{0} \sum_{1 \leqslant j<i} \sum_{l=0}^{r-1} t_{\zeta_{i}^{l} s_{i j} \zeta_{i}^{-l}} \cdot x^{\mu}
\end{aligned}
$$

$$
\begin{aligned}
= & \left(\kappa\left(\mu_{i}+1\right)-\sum_{l=1}^{r / p-1} c_{l p}\left(1-\zeta^{-l p\left(\mu_{i}+1\right)}\right)\right) x^{\mu}-c_{0} \sum_{\substack{1 \leqslant j<i, \mu_{j} \leqslant \mu_{i}, 0 \leqslant l \leqslant r-1}} \zeta^{l\left(\mu_{i}-\mu_{j}\right)} x^{s_{i j} \mu} \\
& -c_{0} \sum_{\substack{1 \leqslant j<i, \mu_{j}<\mu_{i}, 0 \leqslant l \leqslant r-1}} x^{\mu}-c_{0} \sum_{\substack{i<j \leqslant n, \mu_{j} \leqslant \mu_{i}, 0 \leqslant l \leqslant r-1}} x^{\mu}+c_{0} \sum_{\substack{1 \leqslant j<i, 0 \leqslant l \leqslant r-1}} \zeta^{l\left(\mu_{i}-\mu_{j}\right)} x^{s_{i j} \mu}+\text { lower terms } \\
= & \left(\kappa\left(\mu_{i}+1\right)-\sum_{l=1}^{r / p-1} c_{l p}\left(1-\zeta^{-l p\left(\mu_{i}+1\right)}\right)-c_{0} r\left(w_{\mu}(i)-1\right)\right) x^{\mu}+\text { lower terms }
\end{aligned}
$$

where to obtain the last line we used the formula

$$
w_{\mu}(i)=\left|\left\{j<i \mid \mu_{j}<\mu_{i}\right\}\right|+\left|\left\{j>i \mid \mu_{j} \leqslant \mu_{i}\right\}\right|+1
$$

Now, rewriting in terms of the $d_{j} \mathrm{~s}$ from (4.8) proves part (a) of the theorem.
For part (b), simply observe that the coefficient of $\kappa$ in the formula for the action of $z_{i}$ on $x^{\mu}$ is $\mu_{i+1}$; it follows that the $\mathfrak{t}$-eigenspaces are all one dimensional, and hence a simultaneous eigenbasis exists.

Define the weight $\operatorname{wt}(\mu)$ of $\mu \in \mathbb{Z}_{\geqslant 0}^{n}$ to be the $\mathfrak{t}$-homomorphism mapping $z_{i}$ to

$$
\kappa\left(\mu_{i}+1\right)-\left(d_{0}-d_{-\mu_{i}-1}\right)-r\left(w_{\mu}(i)-1\right) c_{0}
$$

and $\zeta_{i}$ to $\zeta^{-\mu_{i}}$. Let $S_{n}$ act on $\mathbb{Z}_{\geqslant 0}^{n}$ by permuting coordinates, and define operators $\phi$ and $\psi$ as follows:

$$
\left.\begin{array}{rl}
\phi \cdot\left(\mu_{1}, \ldots, \mu_{n}\right) & =\left(\mu_{2}, \mu_{3}, \ldots, \mu_{n}, \mu_{1}+1\right)  \tag{6.5}\\
\psi \cdot\left(\mu_{1}, \ldots, \mu_{n}\right) & =\left(\mu_{n}-1, \mu_{1}, \ldots, \mu_{n-1}\right)
\end{array}\right\}
$$

Lemma 6.2. The action of the intertwiners on the basis $f_{\mu}$ is given by

$$
\sigma_{i} \cdot f_{\mu}= \begin{cases}f_{s_{i}} \cdot \mu & \text { if } \mu_{i}<\mu_{i+1} \text { or } \mu_{i} \neq \mu_{i+1} \bmod r  \tag{6.6}\\ 0 & \text { if } \mu_{i}=\mu_{i+1} \\ \frac{\left(\delta-r c_{0}\right)\left(\delta+r c_{0}\right)}{\delta^{2}} f_{s_{i} \cdot \mu} & \text { if } \mu_{i}=\mu_{i+1} \bmod r \text { and } \mu_{i}>\mu_{i+1}\end{cases}
$$

where

$$
\begin{gather*}
\delta=\kappa\left(\mu_{i}-\mu_{i+1}\right)-c_{0} r\left(w_{\mu}(i)-w_{\mu}(i+1)\right), \\
\Phi \cdot f_{\mu}=f_{\phi \cdot \mu}, \tag{6.7}
\end{gather*}
$$

and

$$
\Psi \cdot f_{\mu}= \begin{cases}0 & \text { if } \mu_{n}=0  \tag{6.8}\\ \left(\kappa \mu_{n}-\left(d_{0}-d_{-\mu_{n}}\right)-c_{0} r\left(w_{\mu}(n)-1\right)\right) f_{\psi \cdot \mu} & \text { if } \mu_{n} \neq 0\end{cases}
$$

Proof. We will establish the formulae for $\sigma_{i}$; the formulae for $\Phi$ and $\Psi$ are proved in an analogous fashion. If $\mu_{i}<\mu_{i+1}$, then for all $\nu \leqslant \mu$ one has $s_{i} \cdot \nu \leqslant s_{i} \cdot \mu$ and it follows that the leading term of $\sigma_{i} \cdot f_{\mu}$ is $x^{s_{i} \cdot \mu}$. Since $\sigma_{i} \cdot f_{\mu}$ is a $\mathfrak{t}$-eigenvector by Lemma 5.3 , we have $\sigma_{i} \cdot f_{\mu}=f_{s_{i} \cdot \mu}$. If $\mu_{i}>\mu_{i+1}$ then by Lemma 5.2 one has

$$
\begin{aligned}
\sigma_{i} \cdot f_{\mu} & =\sigma_{i}^{2} \cdot f_{s_{i} \cdot \mu} \\
& =\frac{\left(z_{i}-z_{i+1}-c_{0} \pi_{i}\right)\left(z_{i}-z_{i+1}+c_{0} \pi_{i}\right)}{\left(z_{i}-z_{i+1}\right)^{2}} f_{s_{i} \cdot \mu} \\
& = \begin{cases}f_{s_{i} \cdot \mu} & \text { if } \mu_{i} \neq \mu_{i+1} \bmod r \\
\frac{\left(\delta-r c_{0}\right)\left(\delta+r c_{0}\right)}{\delta^{2}} f_{s_{i} \cdot \mu} & \text { if } \mu_{i}=\mu_{i+1} \bmod r\end{cases}
\end{aligned}
$$

Corollary 6.3. Suppose that $\kappa=1$. Then the $\mathfrak{t}$-eigenspaces of $M(\mathbf{1})$ are all one dimensional provided that $c_{0} \notin \bigcup_{j=1}^{n}(1 / j) \mathbb{Z}_{>0}$.

Proof. We assume there is a two-dimensional $\mathfrak{t}$-eigenspace and prove that $c_{0} \in$ $\bigcup_{j=1}^{n}(1 / j) \mathbb{Z}_{>0}$. Let $\mu, \nu \in \mathbb{Z}_{\geqslant 0}^{n}$ be distinct and assume that $\mathrm{wt}(\mu)=\mathrm{wt}(\nu)$; since $\mathrm{wt}(w \cdot \mu)=w \cdot \operatorname{wt}(\mu)$ for all $w \in S_{n}$, we may assume that $\mu=\mu_{+}$is a partition. Write $w=w_{\nu}$. Thus, $\mu_{i}-\mu_{i+1}=\nu_{i}-\nu_{i+1} \bmod r$ for $1 \leqslant i \leqslant n-1$ and

$$
\begin{equation*}
\mu_{i}-\nu_{i}=r(n-i+1-w(i)) c_{0} \tag{6.9}
\end{equation*}
$$

for $1 \leqslant i \leqslant n$. Since $\mu \neq \nu, c_{0} \in \mathbb{Q}$ is a rational number. Let $i$ be minimal with $w(i) \neq n-i+1$. Then $w(i)<n-i+1$ and there is some $k>i$ with $w(k)=n-i+1$. Therefore, if $c_{0}<0$, then

$$
\left.\begin{array}{rl}
\mu_{i}-\nu_{i} & =r(n-i+1-w(i)) c_{0}<0  \tag{6.10}\\
\mu_{k}-\nu_{k} & =r(n-k+1-(n-i+1)) c_{0}>0
\end{array}\right\}
$$

whence $\mu_{i}<\nu_{i}$ and $\mu_{k}>\nu_{k}$. But $\mu_{k}>\nu_{k} \geqslant \nu_{i}>\mu_{i}$ contradicts $\mu=\mu_{+}$, and it follows that $c_{0}>0$. Now for $1 \leqslant i \leqslant n-1$ we have

$$
\begin{align*}
\frac{\mu_{i}-\nu_{i}-\left(\mu_{i+1}-\nu_{i+1}\right)}{r} & =(n-i+1-w(i)-(n-i-w(i+1))) c_{0} \\
& =(1+w(i+1)-w(i)) c_{0} \tag{6.11}
\end{align*}
$$

and the corollary follows unless $w(i+1)-w(i)=-1$ for $1 \leqslant i \leqslant n-1$. But in that case $w=w_{0}$ and $\mu=\nu$, which is a contradiction.

In fact, the preceding corollary can be sharpened somewhat: provided that either $p=1$ or $n$ does not divide $r$, the $\mathfrak{t}$-eigenspaces are one dimensional as long as

$$
c_{0} \notin \bigcup_{j=1}^{n-1}(1 / j) \mathbb{Z}_{>0}
$$

We will not need this fact in this paper.

## 7. Koszul resolutions of some finite-dimensional $\mathbb{H}$-modules

We assume for the rest of the paper that $r>1$. For $1 \leqslant k \leqslant n$ and $j \in \mathbb{Z}_{>0}$ with $j \neq 0 \bmod r$ define (affine) hyperplanes

$$
\begin{equation*}
H_{j, k}=\left\{\left(c_{0}, d_{1}, \ldots, d_{r / p-1}\right) \mid d_{0}-d_{-j}+r c_{0}(n-k)=j\right\} \subseteq \mathbb{C}^{r / p} \tag{7.1}
\end{equation*}
$$

and, for $x \in(1 / n) \mathbb{Z}_{>0}$,

$$
\begin{equation*}
H_{x}=\left\{\left(c_{0}, d_{1}, \ldots, d_{r / p-1}\right) \mid c_{0}=x\right\} \tag{7.2}
\end{equation*}
$$

The hyperplane $H_{j, 1}$ was introduced (modulo different conventions for the parameters) in [6], where it was called $E_{j}$. Chmutova and Etingof [6, Theorems 4.2 and 4.3] have proved that there is a finite-dimensional quotient of $M(\mathbf{1})$ when the parameter lies on $H_{j, 1}$ for $j \neq 0 \bmod r$, and that if $p=1$, this quotient is irreducible for generic choices of the parameters. Also, Dunkl and Opdam have proved $[\mathbf{9}, \S 3.4]$ that $M(\mathbf{1})$ is reducible exactly if the parameter is on some $H_{j, k}$ for some positive $j \neq 0$ and $1 \leqslant k \leqslant n \bmod r$ or $H_{x}$ for some $x \in(1 / j) \mathbb{Z}_{>0}-\mathbb{Z}$ with $2 \leqslant j \leqslant n$. The following theorem describes the structure of the module $M(\mathbf{1})$ in the case in which gr $L(\mathbf{1})$ is the quotient of the diagonal co-invariant ring predicted by Haiman. It has the advantage of working for arbitrary divisors $p$ or $r$ : this is what makes our strengthening of Vale's result possible.

Theorem 7.1. Suppose that $\kappa=1$, that $k \in \mathbb{Z}_{>0}$ with $k \neq 0 \bmod r$, that $\left(c_{0}, d_{1}, \ldots, d_{r / p-1}\right) \in H_{k, 1}$ and that the parameters do not lie on any other hyperplane $H_{l, j}$ or $H_{x}$ for $1 \leqslant l \leqslant n, j \in \mathbb{Z}_{>0}$ and $x \in(1 / n) \mathbb{Z}_{>0}$. Then the unique proper submodule of $M(\mathbf{1})$ is

$$
\mathbb{C}\left\{f_{\lambda} \mid \lambda \text { has at least one part of size at least } k\right\} .
$$

Proof. By Corollary 6.3 the $\mathfrak{t}$-eigenspaces of $M(\mathbf{1})$ are all one dimensional, and hence the Jack polynomials $f_{\mu}$ are all well defined. Suppose that $M$ is a proper non-zero submodule of $M(\mathbf{1})$. Then $M$ contains $f_{\mu}$ for some $\mu \in \mathbb{Z}_{\geqslant 0}^{n}$. By our assumption on the parameters and Lemma 6.2, $\sigma_{i} \cdot f_{\mu}$ is a non-zero multiple of $f_{s_{i} \cdot \mu}$ whenever $\mu_{i} \neq \mu_{i+1}$, and it follows that $M$ also contains $f_{s_{i} \cdot \mu}$ for all $1 \leqslant i \leqslant n-1$. Hence, $M$ contains $f_{\mu_{-}}$, where $\mu_{-}$is the non-decreasing rearrangement of $\mu$. By Lemma 6.2, we have $\Psi \cdot f_{\mu}=0$ exactly if $\mu_{n}=0$ or

$$
\begin{equation*}
\mu_{n}=d_{0}-d_{-\mu_{n}}+r\left(w_{\mu}(n)-1\right) c_{0} . \tag{7.3}
\end{equation*}
$$

The latter equation holds exactly if $\mu_{n}=k$ and $w_{\mu}(n)=n$ or, equivalently, exactly if $\mu_{n}=k$ is strictly larger than all other parts of $\mu$. It follows that if all the parts of $\mu$ are of size less than $k$, then $M$ contains $f_{0}=1$, contradicting the fact that $M$ is a proper submodule. On the other hand, if $\mu$ has at least one part of size $k$, it follows from the preceding discussion that by applying an appropriate sequence of intertwiners to $f_{\mu}$ we may obtain a non-zero multiple of $f_{\nu}$, where $\nu=(k, 0, \ldots, 0)$. Since $f_{\nu}$ generates $\mathbb{C}\left\{f_{\lambda} \mid \lambda\right.$ has at least one part of size at least $\left.k\right\}$ as an $\mathbb{H}$-module the result follows.

In [16, Theorem 7.5] the author generalizes Theorem 7.1 to the case of a Verma module $M(V)$ with one-dimensional t-eigenspaces, giving a combinatorial description of the submodule structure (which can be much more intricate than the situation we study in this paper).

## 8. Diagonal co-invariants for $G(r, p, n)$

We continue to assume that $r>1$. The Coxeter number of $G(r, p, n)$ is

$$
h= \begin{cases}r(n-1)+r / p & \text { if } p<r  \tag{8.1}\\ r(n-1) & \text { if } p=r\end{cases}
$$

This agrees with the usual definition of the Coxeter number (the largest degree of a basic invariant) when $r>1$ and $p=1$ or $p=r$. The following theorem constructs an analogue for the groups $G(r, p, n)$ of the quotient of the diagonal co-invariant ring discovered by Gordon in [12]. For $p<r$, a very similar theorem is proved in [25]. Our techniques (which are conceptually very similar to those of [5], but work directly in $\mathbb{H}$ ) allow us to handle the case $p=r$ in the same way as $p<r$.

Lemma 8.1. Let $m$ be a positive integer not divisible by $r$ and let $V$ be the representation $\mathbb{C}\left\{x_{1}^{m}, \ldots, x_{n}^{m}\right\}$. Then $V$ is free. If $m=h+1$ and $e_{1}, \ldots, e_{n}$ are the exponents of $V$, then the multisets $\left\{h+1-e_{i}\right\}_{i=1}^{n}$ and $\left\{d_{i}\right\}_{i=1}^{n}$ are equal.

Proof. Let $\bar{m}$ and $m^{\prime}$ be the integers determined by

$$
\begin{equation*}
0 \leqslant \bar{m}<r, \quad 0 \leqslant m^{\prime}<r / p, \quad \bar{m}=m \bmod r \quad \text { and } \quad m^{\prime}=m \bmod r / p \tag{8.2}
\end{equation*}
$$

Observe that the representation $\Lambda^{n} V$ is $\epsilon \delta^{-m}$, where $\epsilon$ and $\delta$ are the one-dimensional $G(r, 1, n)$-representations determined by $\epsilon\left(\zeta_{i}^{l} s_{i} j \zeta_{i}^{-l}\right)=-1, \epsilon\left(\zeta_{i}^{l}\right)=1, \delta\left(\zeta_{i}^{l} s_{i} j \zeta_{i}^{-l}\right)=1$ and $\delta\left(\zeta_{i}^{l}\right)=\zeta^{l}$. This is carried by the non-zero element

$$
\left(x_{1} \cdots x_{n}\right)^{m^{\prime}} \prod_{1 \leqslant i<j \leqslant n}\left(x_{i}^{r}-x_{j}^{r}\right)
$$

of the ordinary co-invariant ring.
For $1 \leqslant i, j \leqslant n$, let

$$
\begin{equation*}
f_{i, j}=x_{j}^{(i-1) r+\bar{m}} \text { and put } v_{j}=x_{1}^{r-\bar{m}+m^{\prime}} \cdots x_{j}^{m^{\prime}} \cdots x_{n}^{r-\bar{m}+m^{\prime}} \tag{8.3}
\end{equation*}
$$

When $p=1$, the functions $f_{i, j}$ for $1 \leqslant j \leqslant n$ span a copy of $V$, and, when $p>1$, $v_{1}, \ldots, v_{n}$ span a copy of $V$. One computes

$$
\begin{equation*}
\operatorname{det}\left(f_{i, j}\right)_{i, j=1}^{n}=\left(x_{1} \cdots x_{n}\right)^{\bar{m}} \prod_{1 \leqslant i<j \leqslant n}\left(x_{i}^{r}-x_{j}^{r}\right) \tag{8.4}
\end{equation*}
$$

and if $A$ is the matrix whose $n$th row is $v_{1}, v_{2}, \ldots, v_{n}$ and whose $i$ th row for $1 \leqslant i<n$ is $f_{i, 1}, f_{i, 2}, \ldots, f_{i, n}$, then

$$
\begin{equation*}
\operatorname{det}(A)=(-1)^{n}\left(x_{1} \cdots x_{n}\right)^{m^{\prime}} \prod_{1 \leqslant i<j \leqslant n}\left(x_{i}^{r}-x_{j}^{r}\right) \tag{8.5}
\end{equation*}
$$

It follows by [21, Theorem 3.1] that $V$ is free and the exponents of $V$ are

$$
\begin{equation*}
e_{i}(V)=\bar{m}+(i-1) r \text { for } 1 \leqslant i \leqslant n \quad \text { if } p=1 \tag{8.6}
\end{equation*}
$$

and

$$
\left.\begin{array}{rl}
e_{i}(V) & =\bar{m}+(i-1) r \quad \text { for } 1 \leqslant i \leqslant n-1  \tag{8.7}\\
e_{n}(V) & =(n-1)(r-\bar{m})+n m^{\prime} \quad \text { if } p>1
\end{array}\right\}
$$

The degrees of $G(r, p, n)$ are $r, 2 r, \ldots,(n-1) r, n(r / p)$ if $p<r$ and $r, 2 r, \ldots,(n-1) r, n$ if $p=r$. When $m=h+1$ it is straightforward to verify the last claim.

Theorem 8.2. Suppose that $G(r, p, n)$ acts irreducibly on $\mathbb{C}^{n}$. With $h$ as in (8.1) and $V=\mathbb{C}\left\{x_{1}^{h+1}, \ldots, x_{n}^{h+1}\right\}$, there is a $W$-equivariant quotient $L$ of the diagonal co-invariant ring $R$ of $G(r, p, n)$ such that, for each $w \in W$,

$$
\sum \operatorname{tr}\left(w,\left(L \otimes \Lambda^{n} V\right)_{i}\right) t^{i}=\frac{\operatorname{det}\left(1-t^{h+1} w_{V}\right)}{\operatorname{det}\left(1-t w_{\mathfrak{h}^{*}}\right)}
$$

where $w_{V}$ and $w_{\mathfrak{h}^{*}}$ denote $w$ regarded as an endomorphism of $V$ and $\mathfrak{h}^{*}$, respectively. The image of $S\left(\mathfrak{h}^{*}\right)$ in $L$ is isomorphic to the ordinary co-invariant ring.

Proof. The theorem will follow from Theorem 3.2, with $L=\operatorname{gr} L(\mathbf{1}) \otimes \Lambda^{n} V^{*}$, once we verify its hypotheses. Let $\mu_{i} \in \mathbb{Z}_{\geqslant 0}^{n}$ have an $h+1$ in the $i$ th position and 0s elsewhere. Then one checks that with $c_{s}=(h+1) / h$ for all reflections $s \in G(r, p, n)$ the hypotheses as in Theorem 7.1 are satisfied for $k=h+1$. Thus, the radical of $M(\mathbf{1})$ is generated by $\mathbb{C}\left\{f_{\mu_{1}}, \ldots, f_{\mu_{n}}\right\}$. Lemma 6.2 shows that, as $W$-modules,

$$
\begin{equation*}
\mathbb{C}\left\{f_{\mu_{1}}, \ldots, f_{\mu_{n}}\right\} \cong V=\mathbb{C}\left\{x_{1}^{h+1}, \ldots, x_{n}^{h+1}\right\} \tag{8.8}
\end{equation*}
$$

Thus, the hypotheses of Lemma 3.1 hold, with $k=h+1$. Lemma 8.1 shows that the remaining hypotheses of Theorem 3.2 hold.

For an arbitrary irreducible complex reflection group $W$ we define the 'Coxeter' number of $W$ to be

$$
\begin{equation*}
h=\frac{N+N^{*}}{n} \tag{8.9}
\end{equation*}
$$

where $n$ is the dimension of the reflection representation of $W, N$ is the number of reflections in $W$ and $N^{*}$ is the number of reflecting hyperplanes for $W$. This definition agrees with (8.1) for the groups $G(r, p, n)$ whenever they are irreducible. By a straightforward modification of [3, Proposition 2.3], when $c=1 / h$ there is a one-dimensional $\mathbb{H}$-module with a Bernstein-Gelfand-Gelfand (BGG) resolution.

Question 8.3. Is it possible that, for every complex reflection group $W$ and every integer $m$ coprime to the 'Coxeter' number $h$, when $c=(m / h)$ the $\mathbb{H}$-module $L(\mathbf{1})$ is $m^{n}$ dimensional with BGG resolution

$$
\begin{equation*}
0 \rightarrow M\left(\Lambda^{n} V\right) \rightarrow \cdots \rightarrow M\left(\Lambda^{1} V\right) \rightarrow M(\mathbf{1}) \rightarrow L(\mathbf{1}) \rightarrow 0 \tag{8.10}
\end{equation*}
$$

where $V$ is an irreducible $\mathbb{C} W$-module of dimension $n$ ?

This question is related to [4, Conjecture 4.3]: Bessis and Reiner conjecture that for an irreducible complex reflection group of dimension $n$ that can be generated by $n$ reflections, there is a homogeneous system of parameters in each degree $\pm 1 \bmod h$ that carries either the reflection representation or its dual. The existence of such a homogeneous system of parameters implies an interpretation of the $q$-Fuss/Catalan numbers as Hilbert series (see [1] for a survey of 'Catalan phenomena' and non-crossing partitions). We expect that, at parameters $c_{s}=1+1 / h$, if $W$ can be generated by $n$ reflections, then $L(\mathbf{1})$ gives rise to a nice quotient of the diagonal co-invariant ring; the results of $[\mathbf{2 4}, \S 5]$ are sure to be relevant here.

## Note added in proof

Question 8.3 is answered in [13], assuming that the Hecke algebra of $W$ is free of rank $|W|$.

Acknowledgements. The bulk of this paper is based on a thesis [14] written at the University of Wisconsin under the direction of Arun Ram. I am greatly indebted to him for teaching me about rational Cherednik algebras and for suggesting the problems that motivated this work. I am also grateful to Drew Armstrong, Ezra Miller, Vic Reiner and Peter Webb for many interesting discussions during the time when this paper was written. Finally, I thank Richard Vale for correspondence that stimulated an improvement of the results and Iain Gordon for pointing out that Rouquier's results [24] are relevant to the Bessis-Reiner conjecture on $W$-Catalan numbers.
