The aim of the work: We tried to find the intercorrelations between the : intensity of symptoms of eating disorders in two groups of girls those who used internet pornography and the second one that not used. We further analyzed the group of girls that used internet pornography concerning symptoms of eating disorders and family factors.

The study group: 186 girls in age 16 to 19.

Methods: We used the Inventory that divided the girls into two groups - 29 girls that used internet pornography and 156 who not used Eating Disorders Inventory (by Garner, Olmsted & Polivy) and our own Inventory of Attitudes to Eating Disorders.

Results and conclusions:

1. The girls from the group that used internet pornography more often than the control group girls use laxatives, abuse alcohol and binge.
2. The girls from the group that used internet pornography experience significantly more common emotional, physical and sexual abuse, lack of acceptance, rejection, and more often defend mothers against the aggression of their fathers.
3. More girls from the group that used internet pornography made coalitions with their mothers against their fathers
