#### Abstract

We give an upper bound on the volume $\operatorname{vol}\left(P^{*}\right)$ of a polytope $P^{*}$ dual to a $d$-dimensional lattice polytope $P$ with exactly one interior lattice point in each dimension $d$. This bound, expressed in terms of the Sylvester sequence, is sharp and achieved by the dual to a particular reflexive simplex. Our result implies a sharp upper bound on the volume of a $d$-dimensional reflexive polytope. Translated into toric geometry, this gives a sharp upper bound on the anti-canonical degree $\left(-K_{X}\right)^{d}$ of a $d$-dimensional Fano toric variety $X$ with at worst canonical singularities.

## 1. Introduction

### 1.1. Background and results

Let $N \cong \mathbb{Z}^{d}$ be a lattice of rank $d$. A convex polytope $P \subset N_{\mathbb{R}}$, where $N_{\mathbb{R}}:=N \otimes_{\mathbb{Z}} \mathbb{R} \cong \mathbb{R}^{d}$, is called a lattice polytope if the vertices vert $(P)$ of $P$ are contained in $N$. Two lattice polytopes $P, Q \subset N_{\mathbb{R}}$ are said to be unimodular equivalent if there exists an affine lattice automorphism $\varphi \in \mathrm{GL}_{d}(\mathbb{Z}) \ltimes \mathbb{Z}^{d}$ of $N$ such that $\varphi_{\mathbb{R}}(P)=Q$. Unless stated otherwise, we regard lattice polytopes as being defined only up to unimodular equivalence.

Let $P \subset N_{\mathbb{R}}$ be a lattice polytope of dimension $d$ (that is, $P$ is of maximum dimension in $N_{\mathbb{R}}$ ) containing exactly one lattice point in its (strict) interior: that is, $|\operatorname{int}(P) \cap N|=1$. We can assume that this interior point is the origin $\mathbf{0} \in N$. For reasons explained in Section 1.2 below, we call $P$ a canonical Fano polytope. As a consequence of results by Hensley [9, Theorem 3.6] and Lagarias-Ziegler [15, Theorem 2], there are finitely many canonical Fano polytopes (up to unimodular equivalence) in each dimension $d$.

Canonical Fano polytopes in dimensions $d \leq 3$ have been classified [10], and we find that $\operatorname{vol}(P) \leq 12$. For $d \geq 4$, it is conjectured that the volume of a $d$-dimensional canonical Fano polytope is bounded by

$$
\begin{equation*}
\operatorname{vol}(P) \leq \frac{1}{d!} 2\left(s_{d}-1\right)^{2} \tag{1.1}
\end{equation*}
$$

where $s_{i}$ denotes the $i$ th term of the Sylvester sequence:

$$
s_{1}:=2, \quad s_{i+1}:=s_{1} \cdots s_{i}+1 \text { for } i \in \mathbb{Z}_{\geq 1} .
$$

Moreover, the case of equality in equation (1.1) is expected to be attained only by the canonical Fano simplex

$$
R_{(d)}:=S_{(d)}-\sum_{i=1}^{d} e_{i}, \quad \text { where } S_{(d)}:=\operatorname{conv}\left\{\mathbf{0}, 2\left(s_{d}-1\right) e_{d}, s_{d-1} e_{d-1}, \ldots, s_{1} e_{1}\right\}
$$

Here $\left\{e_{1}, \ldots, e_{d}\right\}$ is a basis of $N$. This conjecture is hinted at in [15, 19, 21], explicitly stated in [16, Conjecture 1.7] and proved by Averkov-Krümpelmann-Nill [3] for the case when $P$ is a canonical Fano simplex. The conjecture remains open for a general canonical Fano polytope. The current best upper bound on the volume of a canonical Fano polytope that is not a simplex is established in [3, Theorem 2.7] (improving upon a result by Pikhurko [17]); however, this is presumed to be far from sharp:

$$
\operatorname{vol}(P) \leq\left(s_{d+1}-1\right)^{d}
$$

Instead of bounding $\operatorname{vol}(P)$, it is also natural to consider the volume of the dual polytope $P^{*}$ (see Section 1.4 for the definition of the dual polytope). The main result of this paper is:

Theorem 1.1. Let $P \subset N_{\mathbb{R}}$ be a d-dimensional canonical Fano polytope, where $d \geq 4$. Then

$$
\operatorname{vol}\left(P^{*}\right) \leq \frac{1}{d!} 2\left(s_{d}-1\right)^{2}
$$

with equality if and only if $P=R_{(d)}^{*}$.
In three dimensions, the expected bound $\operatorname{vol}\left(P^{*}\right) \leq 12$ is proved in [10, Theorem 4.6]. In this case, however, equality is obtained by the duals of two distinct simplices:

$$
\begin{equation*}
P_{1,1,1,3}=\operatorname{conv}\left\{e_{1}, e_{2}, e_{3},-e_{1}-e_{2}-3 e_{3}\right\} \quad \text { and } \quad P_{1,1,4,6}=R_{(3)}^{*} . \tag{1.2}
\end{equation*}
$$

The analogue of Theorem 1.1 is proved in [3, Theorem 2.5(b)] for $d$-dimensional canonical Fano simplices.

Probably one of the most studied classes of canonical Fano polytopes is the reflexive polytopes, consisting of those $P \subset N_{\mathbb{R}}$ such that the dual $P^{*}$ is also a canonical Fano polytope (for a brief survey, see [12]). Note that $R_{(d)}$ is a reflexive simplex [16]. An immediate consequence of Theorem 1.1 is a proof of the conjectured inequality in equation (1.1) in the case of reflexive polytopes:

Corollary 1.2. Let $P \subset N_{\mathbb{R}}$ be a d-dimensional reflexive polytope, where $d \geq 4$. Then

$$
\operatorname{vol}(P) \leq \frac{1}{d!} 2\left(s_{d}-1\right)^{2}
$$

with equality if and only if $P=R_{(d)}$.
The analogue of Corollary 1.2 in the case of reflexive simplices is proved in [16, Theorem A].

### 1.2. Toric geometry and Fano varieties

Canonical Fano polytopes arise naturally in algebraic geometry. To each $d$-dimensional canonical Fano polytope $P \subset N_{\mathbb{R}}$, we can associate a $d$-dimensional projective toric variety $X_{P}$ whose fan is given by the cones in $N_{\mathbb{R}}$ spanning the faces of $P$ (here we require that the unique interior point of $P$ is taken to be the origin $\mathbf{0}$ of $N$ ). This variety is Fano - recall that a variety $X$ is Fano if its anti-canonical divisor $-K_{X}$ is ample - and has at worst canonical singularities. In fact, this construction is reversible, and there exists a one-to-one correspondence between (unimodular equivalence classes of) canonical Fano polytopes and (isomorphism classes of) Fano toric varieties with at worst canonical singularities. For details on canonical singularities and their importance in algebraic geometry, see [20]; for details on toric geometry, see [8]; and for additional background material, see the survey [12].

The classification of Fano varieties is a long-standing open problem. An important advance would be to bound the degree $\left(-K_{X}\right)^{d}$. In the case when $X$ is nonsingular, the bound

$$
\begin{equation*}
\left(-K_{X}\right)^{d} \leq\left(3\left(2^{d}-1\right)(d+1)^{(d+1)\left(2^{d}-1\right)}\right)^{d} \tag{1.3}
\end{equation*}
$$

was established by Kollár-Miyaoka-Mori [13], although this is almost certainly not sharp. Very little is known when $X$ has canonical singularities; however, Prokhorov [18] proved that if $X$ is a threedimensional Fano with Gorenstein canonical singularities, then the degree is bounded by $\left(-K_{X}\right)^{3} \leq 72$. In this case, the maximum degree is obtained by the two weighted projective spaces $\mathbb{P}(1,1,1,3)$ and $\mathbb{P}(1,1,4,6)$, and these two toric varieties correspond to the two canonical Fano simplices in equation (1.2). It is tempting to conjecture that in higher dimensions, the maximum degree is obtained by a Fano toric variety. Recalling that $\left(-K_{X_{P}}\right)^{d}=d!\operatorname{vol}\left(P^{*}\right)$, Theorem 1.1 provides a sharp bound on the degree when $X$ is toric:

Corollary 1.3. Let $X$ be a d-dimensional Fano toric variety with at worst canonical singularities, where $d \geq 4$. Then

$$
\begin{equation*}
\left(-K_{X}\right)^{d} \leq 2\left(s_{d}-1\right)^{2} \tag{1.4}
\end{equation*}
$$

with equality if and only if $X$ is isomorphic to the weighted projective space

$$
\mathbb{P}\left(1,1,2\left(s_{d}-1\right) / s_{d-1}, \ldots, 2\left(s_{d}-1\right) / s_{1}\right)
$$

This extends [16, Theorem A] and [3, Theorem 2.11], where analogous results are stated when $X$ is a Gorenstein fake weighted projective space and when $X$ is a fake weighted projective space with at worst canonical singularities, respectively. Corollary 1.3 also generalises the three-dimensional bound of [10, Theorem 4.6].

Finally, Corollary 1.3 also has implications for current attempts to classify nonsingular Fano varieties via mirror symmetry [7]. Here the hope is that a nonsingular Fano variety $X$ with $-K_{X}$ very ample has a $\mathbb{Q}$-Gorenstein deformation to a Gorenstein canonical Fano toric variety $X_{P}$. Since this deformation would leave the degree unchanged, the bound of Corollary 1.3 would apply to $X$. It is interesting to note that in this case, the bound in equation (1.4) is significantly smaller than the bound in equation (1.3) of Kollár-Miyaoka-Mori.

### 1.3. Overview of the proof

Our strategy to prove Theorem 1.1 is as follows. In Section 2, we reduce the problem to canonical Fano polytopes satisfying some minimality condition. We observe that such polytopes admit a decomposition into canonical Fano simplices (following [10] and compare with the decomposition used in [14]), for which the statement is already known [3]. In Section 3, we use this decomposition, together with the monotonicity of the normalised volume, to prove Theorem 1.1 in the majority of cases (Corollary 3.1). Finally, the remaining cases are proved in Section 6 using a mixture of integration techniques (developed in Sections 4-5) and explicit classifications.

### 1.4. Notation and terminology

Let $P \subset N_{\mathbb{R}}$ be a lattice polytope of maximum dimension in a rank $d$ lattice $N \cong \mathbb{Z}^{d}$, and let $M:=\operatorname{Hom}_{\mathbb{Z}}(N, \mathbb{Z}) \cong \mathbb{Z}^{d}$ be the lattice dual to $N$. The dual (or polar) polyhedron of $P$ is

$$
P^{*}:=\left\{y \in M_{\mathbb{R}}:\langle y, x\rangle \geq-1 \text { for every } x \in P\right\}
$$

If $\mathbf{0} \in P$, then $P^{*}$ is a convex polytope, although typically $P^{*}$ has rational vertices and so is not a lattice polytope.

Let $P$ and $Q$ be two maximum-dimensional polytopes in $\left(N_{P}\right)_{\mathbb{R}} \cong \mathbb{R}^{p}$ and $\left(N_{Q}\right)_{\mathbb{R}} \cong \mathbb{R}^{q}$, respectively. Suppose that $P$ and $Q$ contain the origin $\mathbf{0}_{P} \in N_{P}$ and $\mathbf{0}_{Q} \in N_{Q}$ of their respective ambient spaces. The free sum (or direct sum) is the maximum-dimensional polytope

$$
P \oplus Q:=\operatorname{conv}\left(\left(P \times\left\{\mathbf{0}_{Q}\right\}\right) \cup\left(\left\{\mathbf{0}_{P}\right\} \times Q\right)\right) \subset \mathbb{R}^{p+q}
$$

The product is the polytope

$$
P \times Q:=\left\{\left(x_{p}, x_{q}\right): x_{p} \in P, x_{q} \in Q\right\} \subset \mathbb{R}^{p+q} .
$$

Free sums and products of polytopes are related via duality by

$$
(P \oplus Q)^{*}=P^{*} \times Q^{*}
$$

On the affine hull $\mathrm{aff}(P)$, there exists a volume form called the relative lattice volume that is normalised by setting the volume of a fundamental parallelepiped of $\operatorname{aff}_{\mathbb{Z}}(P)$ equal to 1 . We denote the relative lattice volume of $P$ by $\operatorname{vol}_{N}(P)$. The volume $\operatorname{Vol}_{N}(P):=\operatorname{dim}(P)!\operatorname{vol}_{N}(P)$ is often called the normalised lattice volume of P. If $N^{\prime} \subseteq N$ is a sublattice of $N$, then for $S \subseteq \operatorname{lin}\left(N^{\prime}\right)$, we have $\operatorname{vol}_{N^{\prime}}(S) \leq \operatorname{vol}_{N}(S)$. If in addition we have that $N^{\prime} \rightarrow N$ splits over $\mathbb{Z}$, then $\operatorname{vol}_{N^{\prime}}(S)=\operatorname{vol}_{N}(S)$.

## 2. Decomposition of minimal polytopes

The case of canonical Fano simplices is already considered in [3]. Our focus is on the case when $P$ is not a simplex. Notice that if $P \subsetneq Q$, then $Q^{*} \subsetneq P^{*}$, and hence $\operatorname{vol}\left(Q^{*}\right)<\operatorname{vol}\left(P^{*}\right)$. It is therefore sufficient to prove Theorem 1.1 for 'small' polytopes $P$ : that is, for the minimal canonical Fano polytopes:

Figure 1. An example of a three-dimensional minimal canonical Fano polytope P, which decomposes into two canonical Fano simplices $S_{1}$ and $S_{2}$ sharing a common vertex $v$. In the notation of Corollary 2.3, $d=3, t=2, d_{1}=d_{2}=2$ and $r_{2}=1$.

Definition 2.1 [10, Definition 2.2]. A $d$-dimensional canonical Fano polytope $P \subset N_{\mathbb{R}}$ is minimal if for each vertex of $P$, the polytope obtained by removing this vertex is not a $d$-dimensional canonical Fano polytope: that is, if $\operatorname{conv}(P \cap N \backslash\{v\})$ is not a $d$-dimensional canonical Fano polytope for each $v \in \operatorname{vert}(P)$.

Each canonical Fano polytope $Q$ can be reduced to a minimal polytope $P \subset Q$ via successive removal of vertices. Of course, $P$ need not be uniquely determined. Minimal canonical Fano polytopes admit a decomposition in terms of lower-dimensional minimal canonical Fano simplices:

Proposition 2.2 [10, Proposition 3.2]. Let $P$ be a minimal canonical Fano d-polytope that is not a simplex. Then there exists a minimal canonical Fano $k$-simplex $S$ contained in $P$ with $\operatorname{vert}(S) \subset \operatorname{vert}(P)$ for some $1 \leq k<d$. For any such $S$, there exists a minimal canonical Fano $(d-k+s)$-polytope $P^{\prime}$ with $\operatorname{vert}\left(P^{\prime}\right) \subset \operatorname{vert}(P)$ such that $P=\operatorname{conv}\left(S \cup P^{\prime}\right), s=\left|\operatorname{vert}(S) \cap \operatorname{vert}\left(P^{\prime}\right)\right|$ and $0 \leq s<k$.

For brevity, we write ' $d$-polytope' rather than 'polytope of dimension $d$ ' and ' $k$-simplex' rather than 'simplex of dimension $k$ '.

Corollary 2.3. Let $P$ be a minimal canonical Fano d-polytope that is not a simplex. Then for some $2 \leq t \leq d$, there exist minimal canonical Fano simplices $S_{1}, \ldots, S_{t}$ such that $P=\operatorname{conv}\left(S_{1} \cup \cdots \cup S_{t}\right)$, where $\operatorname{dim}\left(S_{i}\right)=d_{i} \geq 1$ and $\operatorname{vert}\left(S_{i}\right) \subset \operatorname{vert}(P)$, for each $1 \leq i \leq t$. Set $r_{1}:=0$, and for each $2 \leq i \leq t$, set $r_{i}:=\left|\operatorname{vert}\left(S_{i}\right) \cap \operatorname{vert}\left(P^{(i-1)}\right)\right|$, where $P^{(i-1)}:=\operatorname{conv}\left(S_{1} \cup \cdots \cup S_{i-1}\right)$. Then

$$
\begin{align*}
d_{1}+\cdots+d_{t} & =d+r, & \text { where } r:=r_{1}+\cdots+r_{t} ;  \tag{2.1}\\
r_{i}<d_{i} & \leq d-t+1, & \text { for each } 1 \leq i \leq t ;  \tag{2.2}\\
|\operatorname{vert}(P)| & =d+t . & \tag{2.3}
\end{align*}
$$

An example of this decomposition is illustrated in Figure 1.
Proof. We apply Proposition 2.2 iteratively, at each step choosing $S$ to be of smallest possible dimension. Thus $P$ can be written as $P=\operatorname{conv}\left(S_{1} \cup \cdots \cup S_{t}\right)$ for some $t \geq 1$, where the $S_{i}$ are minimal canonical Fano simplices of dimension $d_{i} \geq 1$ with vert $\left(S_{i}\right) \subseteq \operatorname{vert}(P)$ having $r_{i}$ common vertices with $P^{(i-1)}$, such that $d_{t} \leq d_{t-1} \leq \cdots \leq d_{1}$. The case $P^{(0)}$ is taken to be the empty set, giving $r_{1}=0$. At each step, the dimension of $P^{(i)}$ can be obtained from Proposition 2.2: $\operatorname{dim}\left(P^{(i)}\right)=\operatorname{dim}\left(P^{(i-1)}\right)+\operatorname{dim}\left(S_{i}\right)-r_{i}$. Hence $d=\sum_{i=1}^{t}\left(d_{i}-r_{i}\right)$, so equation (2.1) holds. Once again using Proposition 2.2, since $\operatorname{dim}\left(S_{i}\right)>r_{i}$, $\operatorname{dim}\left(P^{(i)}\right) \geq \operatorname{dim}\left(P^{(i-1)}\right)+1$. It follows that $t \leq d$, so $d_{1} \leq d-t+1$. Hence our choice of simplices implies equation (2.2). Finally, the number of vertices of $P^{(i)}$ is $\left|\operatorname{vert}\left(P^{(i-1)}\right)\right|+\left|\operatorname{vert}\left(S_{i}\right)\right|-r_{i}$. This implies that $|\operatorname{vert}(P)|=\sum_{i=1}^{t}\left(d_{i}+1\right)-r$, and from equation (2.1), we deduce that equation (2.3) holds.

Notice that equality (2.3), combined with the bound $t \leq d$, implies that a minimal canonical Fano polytope $P$ satisfies $|\operatorname{vert}(P)| \leq 2 d$ (this is known as Steinitz's inequality).

## 3. Bounding the volume of $P^{*}$ via monotonicity of the normalised volume

As noted above, it is sufficient to prove Theorem 1.1 for minimal canonical Fano polytopes that are not simplices. Let $P \subset N_{\mathbb{R}}$ be such a polytope of dimension $d \geq 4$. Fix a decomposition of $P$, and use the notation $t, S_{i}, d_{i}, r_{i}, r$ as defined in Corollary 2.3. In this section, we prove Theorem 1.1 for the majority of decompositions. The decompositions not addressed in this section and whose proof is the focus of Sections 4-5 below are listed in Corollary 3.1.

Corollary 3.1. To prove Theorem 1.1, it is enough to verify that the inequality

$$
\operatorname{vol}\left(P^{*}\right) \leq \frac{1}{d!} 2\left(s_{d}-1\right)^{2}
$$

holds for all minimal canonical Fano polytopes $P \subset N_{\mathbb{R}}$ of dimension $d \geq 4$ whose decomposition into minimal canonical Fano simplices falls into one of the following five cases:

1. $t=2$ and $d_{1}=d_{2}=d-1$; or
2. $t=2, d=4, d_{1}=3$ and $d_{2}=2$; or
3. $t=2, d=5, d_{1}=4$ and $d_{2}=3$; or
4. $t=3, d=4$ and $d_{1}=d_{2}=d_{3}=2$; or
5. $t=3, d=5$ and $d_{1}=d_{2}=d_{3}=3$.

To prove Corollary 3.1, we use the monotonicity of the normalised volume. Let $N_{i}:=\operatorname{lin}_{\mathbb{R}}\left(S_{i}\right) \cap N$ be the sublattice of lattice points in the linear hull of $S_{i}$ (recall that $\mathbf{0} \in \operatorname{int}\left(S_{i}\right)$, so this really is a sublattice) for each $1 \leq i \leq t$. Define the map

$$
\varphi: N_{1} \oplus \cdots \oplus N_{t} \rightarrow N, \quad\left(x_{1}, \ldots, x_{t}\right) \mapsto \sum_{i=1}^{t} x_{i}
$$

Notice that $\varphi$ may not be surjective; however, since its image has the same rank as $N$, the extension $\varphi_{\mathbb{R}}$ of $\varphi$ to a map of vector spaces is surjective. Moreover, $\varphi_{\mathbb{R}}$ gives the following representation of $P$ :

$$
P=\varphi_{\mathbb{R}}\left(S_{1} \oplus \cdots \oplus S_{t}\right)
$$

Let $M, M_{1}, \ldots, M_{t}$ denote the lattices dual to $N, N_{1}, \ldots, N_{t}$, respectively. The map $\varphi_{\mathbb{R}}^{*}$ dual to $\varphi_{\mathbb{R}}$ is an injection, and in particular

$$
P^{*} \cong \varphi_{\mathbb{R}}^{*}\left(P^{*}\right) \subset\left(S_{1} \oplus \cdots \oplus S_{t}\right)^{*}=S_{1}^{*} \times \cdots \times S_{t}^{*}
$$

where $M$ is naturally embedded via $\varphi^{*}$ into $M_{1} \oplus \cdots \oplus M_{t}$. This situation will be studied in more detail in Section 4 . Using the monotonicity of the normalised volume, finding an upper bound for the normalised volume of $S_{1}^{*} \times \cdots \times S_{t}^{*}$ yields an upper bound for the normalised volume of $P^{*}$. Specifically, we know that

$$
\begin{align*}
\operatorname{Vol}_{M}\left(P^{*}\right) & \leq \operatorname{Vol}_{M_{1} \oplus \cdots \oplus M_{t}}\left(S_{1}^{*} \times \cdots \times S_{t}^{*}\right) \\
& =\left(d_{1}+\cdots+d_{t}\right)!\operatorname{vol}_{M_{1} \oplus \cdots \oplus M_{t}}\left(S_{1}^{*} \times \cdots \times S_{t}^{*}\right) \\
& =\left(d_{1}+\cdots+d_{t}\right)!\prod_{i=1}^{t} \operatorname{vol}_{M_{i}}\left(S_{i}^{*}\right)  \tag{3.1}\\
& =\frac{\left(d_{1}+\cdots+d_{t}\right)!}{d_{1}!\cdots d_{t}!} \prod_{i=1}^{t} \operatorname{Vol}_{M_{i}}\left(S_{i}^{*}\right) .
\end{align*}
$$

The normalised volume of $S_{i}^{*}$ is bounded from above (see [10] and [3, Theorem 2.5(b)]):

$$
\operatorname{Vol}_{M_{i}}\left(S_{i}^{*}\right) \leq B_{d_{i}}, \quad \text { with } B_{i}:= \begin{cases}9 & \text { if } i=2, \\ 2\left(s_{d_{i}}-1\right)^{2} & \text { if } i \neq 2 .\end{cases}
$$

Hence the inequality in equation (3.1) becomes

$$
\operatorname{Vol}_{M}\left(P^{*}\right) \leq \frac{\left(d_{1}+\cdots+d_{t}\right)!}{d_{1}!\cdots d_{t}!} \prod_{i=1}^{t} B_{d_{i}}
$$

At this point, Theorem 1.1 would follow from

$$
\begin{equation*}
\frac{\left(d_{1}+\cdots+d_{t}\right)!}{d_{1}!\cdots d_{t}!} \prod_{i=1}^{t} B_{d_{i}}<B_{d} . \tag{3.2}
\end{equation*}
$$

Unfortunately,the inequality in equation (3.2) does not always hold: for example, it fails when $t=2$ and $d_{1}=d_{2}=d-1$, for any $d \geq 3$. Nevertheless, this technique is sufficient to prove Theorem 1.1 for a large number of cases:

Lemma 3.2. The inequality in equation (3.2) - and therefore Theorem 1.1 - holds whenever:

1. $t \geq 3$, with the exception of the following six cases:
(a) $t=3, d=4$ and $d_{1}=d_{2}=d_{3}=2$; or
(b) $t=3, d=5$ and $d_{1}=d_{2}=d_{3}=3$; or
(c) $t=3, d=4, d_{1}=d_{2}=2$ and $d_{3}=1$; or
(d) $t=3, d=5, d_{1}=d_{2}=3$ and $d_{3}=2$; or
(e) $t=3, d=6$ and $d_{1}=d_{2}=d_{3}=4$; or
(f) $t=4, d=5$ and $d_{1}=d_{2}=d_{3}=d_{4}=2$;
2. $t=2$, with the exceptions of the following three cases:
(a) $d_{1}=d_{2}=d-1$; or
(b) $d=4, d_{1}=3$ and $d_{2}=2$; or
(c) $d=5, d_{1}=4$ and $d_{2}=3$.

Proof. We prove equation (1) and equation (2) separately but by the same general technique: first we show that the statement is true for large values of $d$; then we check the finite number of remaining values.
(1) Since the quantity

$$
\frac{\left(d_{1}+\cdots+d_{t}\right)!}{d_{1}!\cdots d_{t}!} \prod_{i=1}^{t} B_{d_{i}}
$$

increases as the $d_{i}$ increase, by equation (2.2), it is enough to prove the inequality in equation (3.2) when $d_{i}=d-t+1$ for all $i$. That is, it is sufficient to show that

$$
\begin{equation*}
\frac{(t(d-t+1))!}{(d-t+1)!^{t}}\left(B_{d-t+1}\right)^{t}<B_{d} . \tag{3.3}
\end{equation*}
$$

From $n!\leq 2 \cdot 2^{2} \cdots 2^{n-1}=2^{n(n-1) / 2}$ (which is strict when $n \geq 3$ ), we obtain

$$
\frac{(t(d-t+1))!}{(d-t+1)!^{t}} \leq(t(d-t+1))!<2^{\frac{1}{2} t(d-t+1)(t(d-t+1)-1)} .
$$

Therefore, if the inequality

$$
\begin{equation*}
2^{\frac{1}{2} t(d-t+1)(t(d-t+1)-1)} 2^{t}\left(B_{d-t+1}\right)^{t} \leq B_{d} \tag{3.4}
\end{equation*}
$$

holds, so too does the inequality in equation (3.3).
To prove equation (3.4), we make use of the well-known description due to Aho-Sloane [1, Example 2.5] of the Sylvester sequence in terms of the constant $c \approx 1.2640847353 \ldots$ :

$$
s_{n}=\left\lfloor c^{2^{n}}+\frac{1}{2}\right\rfloor .
$$

Notice that $B_{d}=2\left(s_{d}-1\right)^{2}>\left(s_{d}+1\right)^{2}$ whenever $d \geq 3$. Since $s_{d}+1>c^{2^{d}}$, the right-hand side of equation (3.4) is bounded from below:

$$
B_{d}=2\left(s_{d}-1\right)^{2}>\left(s_{d}+1\right)^{2}>c^{2^{d+1}} .
$$

Moreover, $B_{d-t+1} / 2<c^{2^{d-t+2}}$. Since $c^{3}>2$, the left-hand side of equation (3.4) is bounded from above:

$$
2^{\frac{1}{2} t(d-t+1)(t(d-t+1)-1)} 2^{t}\left(\frac{B_{d-t+1}}{2}\right)^{t}<c^{\frac{3}{2} t(d-t+1)(t(d-t+1)-1)} c^{3 t} c^{2^{d-t+2} t} .
$$

We shall show that $c^{\frac{3}{2} t(d-t+1)(t(d-t+1)-1)} c^{3 t} c^{2^{d-t+2} t} \leq c^{2^{d+1}}$, from which we conclude that the inequality in equation (3.4) holds. Taking $\log _{c}$, we have to verify that the inequality

$$
\frac{3}{2} t(d-t+1)(t(d-t+1)-1)+3 t+2^{d-t+2} t \leq 2^{d+1}
$$

is satisfied. Rewrite this inequality as

$$
3 t(d-t+1)(t(d-t+1)-1)+6 t \leq 2^{d+2}\left(1-\frac{t}{2^{t-1}}\right)
$$

Since $t \geq 3$, by setting $t=3$ in the right-most factor, it is enough to prove that

$$
3 t(d-t+1)(t(d-t+1)-1)+6 t \leq 2^{d} .
$$

Since $t(d-t+1)$ is maximised when $t=(d+1) / 2$, and since $6 t \leq 6 d$, the above inequality is valid when

$$
\frac{3(d+1)}{2}\left(d-\frac{d+1}{2}+1\right)\left(\frac{d+1}{2}\left(d-\frac{d+1}{2}+1\right)-1\right)+6 d \leq 2^{d}
$$

This holds when $d \geq 13$. Recalling that $d$ bounds the quantities $t, d_{1}, \ldots, d_{t}$, we are left with finitely many cases to verify. The inequality in equation (3.2) holds in all but six cases, as listed in the statement.
(2) By the same monotonicity argument used at the beginning of the previous case, we choose $d_{1}$ and $d_{2}$ as large as possible: that is, we fix $d_{1}=d-1$ and $d_{2}=d-2$ (we noted above that the inequality in equation (3.2) is not satisfied when $d_{1}=d_{2}=d-1$ ). The inequality in equation (3.2) becomes

$$
\frac{(2 d-3)!}{(d-2)!(d-1)!} B_{d-2} B_{d-1}<B_{d}
$$

Proceeding as above, we reduce the problem to proving the inequality

$$
3\left(2 d^{2}-7 d+8\right)+2^{d-1}+2^{d} \leq 2^{d+1}
$$

This holds when $d \geq 10$. Removing the assumptions $d_{1}=d-1$ and $d_{2}=d-2$ on $d_{1}$ and $d_{2}$, the finitely many cases for $4 \leq d \leq 9$ can be directly verified against the inequality in equation (3.2). We find the exceptional cases listed in the statement of the lemma.

Proof of Corollary 3.1. By Lemma 3.2, we need to show that proving Theorem 1.1 for all decompositions listed in the statement of Corollary 3.1 also proves it in these four cases:

1. $t=3, d=4, d_{1}=d_{2}=2$ and $d_{3}=1$; or
2. $t=3, d=5, d_{1}=d_{2}=3$ and $d_{3}=2$; or
3. $t=3, d=6$ and $d_{1}=d_{2}=d_{3}=4$; or
4. $t=4, d=5$ and $d_{1}=d_{2}=d_{3}=d_{4}=2$.

In each case, we have that either $t=3$ or $t=4$. By Corollary 2.3, we can express $P$ as $P=P^{\prime} \cup S_{t}$, where $P^{\prime}=S_{1} \cup \cdots \cup S_{t-1}$ is a minimal polytope of dimension $d^{\prime}$ decomposed into $t^{\prime}=t-1$ minimal simplices. Note that in all four cases, $d^{\prime}=d-1$. We now proceed exactly as in the first part of this section. Let $N^{\prime}:=\operatorname{lin}_{\mathbb{R}}\left(P^{\prime}\right) \cap N$ be the sublattice of $N$ of lattice points in the linear hull of $P^{\prime}$. We define the map $\varphi^{\prime}: N^{\prime} \oplus N_{t} \rightarrow N$ by $\left(x_{1}, x_{2}\right) \mapsto x_{1}+x_{2}$, whose extension $\varphi_{\mathbb{R}}$ to a map of vector spaces is surjective and gives the following representation of $P$ :

$$
P=\varphi_{\mathbb{R}}\left(P^{\prime} \oplus S_{t}\right)
$$

Let $M^{\prime}$ denote the lattice dual to $N^{\prime}$. The map $\left(\varphi^{\prime}\right)_{\mathbb{R}}^{*}$ dual to $\left(\varphi^{\prime}\right)_{\mathbb{R}}$ is an injection, and in particular

$$
P^{*} \cong\left(\varphi^{\prime}\right)_{\mathbb{R}}^{*}\left(P^{*}\right) \subset\left(P^{\prime} \oplus S_{t}\right)^{*}=\left(P^{\prime}\right)^{*} \times S_{t}^{*} .
$$

As in equation (3.1), by the monotonicity of the normalised volume,

$$
\begin{equation*}
\operatorname{Vol}_{M}\left(P^{*}\right) \leq \frac{\left(d^{\prime}+d_{t}\right)!}{d^{\prime}!d_{t}!} \operatorname{Vol}_{M^{\prime}}\left(\left(P^{\prime}\right)^{*}\right) \operatorname{Vol}_{M_{t}}\left(S_{t}^{*}\right) \tag{3.5}
\end{equation*}
$$

By our assumption and Lemma 3.2, Theorem 1.1 holds for $t^{\prime}=2$ and for $t^{\prime}=3, d^{\prime}=4, d_{1}=d_{2}=d_{3}=2$. Hence, in all four cases, Theorem 1.1 holds for $P^{\prime}$ : that is, $\operatorname{Vol}_{M^{\prime}}\left(\left(P^{\prime}\right)^{*}\right)<B_{d-1}$. Since $\operatorname{Vol}_{M_{t}}\left(S_{t}^{*}\right) \leq B_{d_{t}}$ and $d^{\prime}=d-1$,

$$
\operatorname{Vol}_{M}\left(P^{*}\right)<\frac{\left(d-1+d_{t}\right)!}{(d-1)!d_{t}!} B_{d-1} B_{d_{t}}
$$

Hence it is enough to prove that

$$
\frac{\left(d-1+d_{t}\right)!}{(d-1)!d_{t}!} B_{d-1} B_{d_{t}}<B_{d} .
$$

This inequality can be directly checked in all four cases.

## 4. Slicing minimal polytopes

We now develop the foundations for a finer technique that we use in Section 6 to help prove the remaining cases of Theorem 1.1. In particular, we shall explain how minimal polytopes can be described as a particular union of slices that are products of slices of simplices (see Figure 2). Using this construction, in Section 5, we give a better estimate of the dual volume via integration.

Figure 2. The dual $P^{*}$ of the polytope $P$ from Figure 1, together with the dual triangles $\left(S_{1}^{\prime}\right)^{*} \subset\left(M_{1}^{\prime}\right)_{\mathbb{R}}$ and $\left(S_{2}^{\prime}\right)^{*} \subset\left(M_{2}^{\prime}\right)_{\mathbb{R}}$. In the left-most picture, the grey slice is $H_{1,0} \times H_{2,0}$. We refer to Section 4.2 for the precise definitions.

### 4.1. Embedding the dual polytope

As above, we are in the setup of Corollary 2.3: $P \subset N_{\mathbb{R}}$ is a $d$-dimensional minimal canonical Fano polytope decomposed into minimal canonical Fano simplices $S_{1}, \ldots, S_{t}$ for some $t \geq 2$. We define

$$
\mathcal{V}:=\bigcup_{1 \leq i_{1}<i_{2} \leq t} \operatorname{vert}\left(S_{i_{1}}\right) \cap \operatorname{vert}\left(S_{i_{2}}\right)
$$

to be the set of those vertices of $P$ that occur multiple times amongst the vertices of the $S_{i}$, and we define $\mathcal{V}_{i}:=\mathcal{V} \cap \operatorname{vert}\left(S_{i}\right)$. For example, in Figure 1, we have $\mathcal{V}=\mathcal{V}_{1}=\mathcal{V}_{2}=\{v\}$.

It will be convenient to coarsen the lattice $N$. We note that coarsening the ambient lattice $N$ to a lattice $N^{\prime}$ is an assumption we can make. Indeed, if $P_{M}^{*}$ and $P_{M^{\prime}}^{*}$ denote the duals of $P$ with respect to the lattices $M=N^{*}$ and $M^{\prime}=\left(N^{\prime}\right)^{*}$, respectively, then the volume of $P_{M^{\prime}}^{*}$, is equal to the volume of $P_{M}^{*}$ multiplied by the index of $M^{\prime}$ as a subgroup of $M$ (which is a positive integer).

Let $N_{i}^{\prime}$ denote some sublattice of $N_{i}=\operatorname{lin}_{\mathbb{R}}\left(S_{i}\right) \cap N$ of rank $d_{i}$ with $\mathcal{V}_{i} \subset N_{i}^{\prime}$ (a specific choice of $N_{i}^{\prime}$ will be given in Section 4.2). Notice that $S_{i}$ may no longer be a lattice simplex with respect to $N_{i}^{\prime}$. Therefore, to avoid any confusion, we denote by $S_{i}^{\prime} \subseteq\left(N_{i}^{\prime}\right)_{\mathbb{R}}=\left(N_{i}\right)_{\mathbb{R}}$ the rational simplex with vertices $\operatorname{vert}\left(S_{i}\right)$ with respect to the lattice $N_{i}^{\prime}$. Now, by possibly coarsening the lattice $N$, we may suppose that $N$ is the image of the lattice $N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$ via the map

$$
\begin{align*}
\varphi: N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime} & \rightarrow N \\
\left(x_{1}, \ldots, x_{t}\right) & \mapsto \sum_{i=1}^{t} x_{i} . \tag{4.1}
\end{align*}
$$

Hence we can assume that this map is surjective. Notice that the polytope $P$ may no longer be a lattice polytope with respect to this ambient lattice. We extend the map $\varphi$ to the map of real vector spaces $\varphi_{\mathbb{R}}:\left(N_{1}^{\prime}\right)_{\mathbb{R}} \oplus \cdots \oplus\left(N_{t}^{\prime}\right)_{\mathbb{R}} \rightarrow N_{\mathbb{R}}$. As in the previous section, we can describe $P$ as

$$
P=\varphi_{\mathbb{R}}\left(S_{1}^{\prime} \oplus \cdots \oplus S_{t}^{\prime}\right) .
$$

By definition, $\varphi$ is a surjective map, so we have the exact sequence

$$
0 \rightarrow \operatorname{ker} \varphi \hookrightarrow N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime} \rightarrow N \rightarrow 0
$$

which splits over $\mathbb{Z}$. From equation (2.1), we have that $N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$ splits into parts of rank $d$ and $r$. As a consequence, the dual sequence

$$
0 \rightarrow M \hookrightarrow M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime} \rightarrow(\operatorname{ker} \varphi)^{*} \rightarrow 0
$$

is exact and splits too. Here we used the notation $M_{1}^{\prime}, \ldots, M_{t}^{\prime}$ for the dual lattices of $N_{1}^{\prime}, \ldots, N_{t}^{\prime}$, respectively. Let $(\operatorname{ker} \varphi)^{\perp}$ denote the elements of $M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime}$ vanishing on $\operatorname{ker} \varphi$. By the exactness
of the dual sequence, $\varphi^{*}(M)=(\operatorname{ker} \varphi)^{\perp}$ : that is, the lattices $M$ and $(\operatorname{ker} \varphi)^{\perp}$ are isomorphic via $\varphi^{*}$. In particular, $(\operatorname{ker} \varphi)^{\perp}=\left(M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime}\right) \cap(\operatorname{ker} \varphi)_{\mathbb{R}}^{\perp}$ is a direct summand of $M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime}$ of rank $d$.

By tensoring by $\mathbb{R}$ to extend the maps to the ambient real vector spaces, it follows that the following polytopes are isomorphic as rational polytopes with respect to their respective lattices:

$$
\begin{align*}
P^{*} & \cong \varphi_{\mathbb{R}}^{*}\left(P^{*}\right) \\
& =\left(S_{1}^{\prime} \oplus \cdots \oplus S_{t}^{\prime}\right)^{*} \cap(\operatorname{ker} \varphi)_{\mathbb{R}}^{\perp}  \tag{4.2}\\
& =\left(\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}\right) \cap(\operatorname{ker} \varphi)_{\mathbb{R}}^{\perp}
\end{align*}
$$

We now describe a set of generators of $(\operatorname{ker} \varphi)_{\mathbb{R}}$. For this, let us identify $N_{i}^{\prime}$ with the corresponding direct summand in $N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$. In this way, we can identify $v \in \operatorname{vert}\left(S_{i}^{\prime}\right)$ with $e_{i, v} \in N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$ : that is, $\left(e_{i, v}\right)_{i}=v \in N_{i}^{\prime}$ and $\left(e_{i, v}\right)_{j}=\mathbf{0}_{N_{j}^{\prime}}$ for $j \neq i$. Recall that $\operatorname{dim}_{\mathbb{R}}(\operatorname{ker} \varphi)_{\mathbb{R}}=r$. Let $1 \leq i_{1}<i_{2} \leq t$ and $v \in \mathcal{V}_{i_{1}} \cap \mathcal{V}_{i_{2}}$. We denote by $w_{v, i_{1}, i_{2}}$ the element $e_{i_{2}, v}-e_{i_{1}, v} \in N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$.
Lemma 4.1. With notation as above, $\operatorname{ker} \varphi_{\mathbb{R}}$ is generated by the set

$$
\Omega:=\left\{w_{v, i_{1}, i_{2}} \in N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}: 1 \leq i_{1}<i_{2} \leq t, v \in \mathcal{V}_{i_{1}} \cap \mathcal{V}_{i_{2}}\right\} .
$$

Proof. We prove that the subset

$$
\Omega^{\prime}:=\left\{w_{v, i_{1}, i_{2}} \in \Omega: i_{1}=\max \left\{i: v \in \mathcal{V}_{i}, i<i_{2}\right\}\right\}
$$

of $\Omega$ is a basis of $\operatorname{ker} \varphi_{\mathbb{R}}$. Since for $2 \leq i \leq t$, we have $\left|\left\{w_{v, i_{1}, i} \in \Omega^{\prime}: i_{2}=i\right\}\right|=r_{i}$, this implies that $\left|\Omega^{\prime}\right|=\sum_{i=2}^{t} r_{i}=r$. Hence it is enough to prove that the elements of $\Omega^{\prime}$ are linearly independent.

Denote the elements of $\Omega^{\prime}$ by $\boldsymbol{x}_{1}, \ldots, \boldsymbol{x}_{r}$, where $\boldsymbol{x}_{j}=\left(\left(\boldsymbol{x}_{j}\right)_{1}, \ldots,\left(\boldsymbol{x}_{j}\right)_{t}\right) \in N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$. Assume there exists a nontrivial relation $\mu_{1} \boldsymbol{x}_{1}+\ldots+\mu_{r} \boldsymbol{x}_{r}=\mathbf{0}$ with $\boldsymbol{\mu}:=\left(\mu_{1}, \ldots, \mu_{r}\right) \in \mathbb{R}^{r} \backslash\{\mathbf{0}\}$. Let us define

$$
\operatorname{supp}(\boldsymbol{\mu}):=\left\{j \in\{1, \ldots, r\}: \mu_{j} \neq 0\right\} .
$$

Let $i \in\{1, \ldots, t\}$ be the largest integer such that there exists an integer $j \in \operatorname{supp}(\boldsymbol{\mu})$, an index $1 \leq i_{1}<i$ and a vertex $v \in \mathcal{V}_{i_{1}} \cap \mathcal{V}_{i}$, with $w_{v, i_{1}, i}=\boldsymbol{x}_{j}$. By definition of $i$ and $\Omega^{\prime}$, all elements in $\left\{\left(\boldsymbol{x}_{j}\right)_{i}: j \in \operatorname{supp}(\boldsymbol{\mu}),\left(\boldsymbol{x}_{j}\right)_{i} \neq \mathbf{0}_{N_{i}^{\prime}}\right\} \neq \varnothing$ are pairwise distinct vertices in $\mathcal{V}_{i} \cap \operatorname{vert}\left(P^{(i-1)}\right)$. Hence

$$
\sum_{j \in \operatorname{supp}(\boldsymbol{\mu})} \mu_{j}\left(\boldsymbol{x}_{j}\right)_{i}=\mathbf{0}_{N_{i}^{\prime}}
$$

implies a nontrivial relation of a non-empty subset of the vertices in $\mathcal{V}_{i} \cap \operatorname{vert}\left(P^{(i-1)}\right)$. However, as $S_{i}$ contains the origin in its interior, any proper subset of the set of vertices of $S_{i}$ is linearly independent, so $\mathcal{V}_{i} \cap \operatorname{vert}\left(P^{(i-1)}\right)=\operatorname{vert}\left(S_{i}\right)$. Hence $r_{i}=d_{i}+1$, a contradiction to equation (2.2).

We now apply Lemma 4.1 to equation (4.2):

$$
\begin{align*}
P^{*} & \cong \varphi_{\mathbb{R}}^{*}\left(P^{*}\right) \\
& =\left(\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}\right) \cap(\operatorname{ker} \varphi)_{\mathbb{R}}^{\perp} \\
& =\left\{\left(y_{1}, \ldots, y_{t}\right) \in\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}:\left\langle\left(y_{1}, \ldots, y_{t}\right), \omega\right\rangle=0 \text { for each } \omega \in(\operatorname{ker} \varphi)_{\mathbb{R}}\right\}  \tag{4.3}\\
& =\left\{\left(y_{1}, \ldots, y_{t}\right) \in\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}:\left\langle y_{i_{1}}, e_{i_{1}, v}\right\rangle=\left\langle y_{i_{2}}, e_{i_{2}, v}\right\rangle \text { for each } w_{v, i_{1}, i_{2}} \in \Omega\right\} \\
& =\left\{\left(y_{1}, \ldots, y_{t}\right) \in\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}:\left\langle y_{i_{1}}, e_{i_{1}, v}\right\rangle=\left\langle y_{i_{2}}, e_{i_{2}, v}\right\rangle \text { for each } v \in \mathcal{V}_{i_{1}} \cap \mathcal{V}_{i_{2}}\right\} .
\end{align*}
$$

### 4.2. The integration map

From here onward, we will assume that the decomposition of $P$ into the simplices $S_{i}$ is irredundant: that is, $\mathcal{V}_{i} \subsetneq \operatorname{vert}\left(S_{i}\right)$ for $i=1, \ldots, t$. Under this assumption, we describe a specific choice for $N_{i}^{\prime}$. For
this, we choose a vertex $v_{i} \in \operatorname{vert}\left(S_{i}\right) \backslash \mathcal{V}_{i}$ and set

$$
\widehat{\mathcal{V}}_{i}:=\operatorname{vert}\left(S_{i}\right) \backslash\left\{v_{i}\right\} .
$$

We have $\mathcal{V}_{i} \subset \widehat{\mathcal{V}}_{i}$. We define $N_{i}^{\prime}$ to be the lattice spanned by $\widehat{\mathcal{V}}_{i}$ : that is,

$$
N_{i}^{\prime}:=\left\langle v \in \widehat{\mathcal{V}}_{i}\right\rangle_{\mathbb{Z}}
$$

By construction, the $d_{i}$ vertices in $\widehat{\mathcal{V}}_{i}$ form a lattice basis

$$
\left\{e_{i, v}\right\}_{v \in \hat{\mathcal{V}}_{i}}
$$

of $N_{i}^{\prime}$ (as a sublattice of $N_{1}^{\prime} \oplus \cdots \oplus N_{t}^{\prime}$ ). Note that the vertex $v_{i}$ need not be a lattice point in $N_{i}^{\prime}$. We again assume that $N$ is given as the image of $\varphi$ - see equation (4.1) - and we will refer to $S_{i}$ as $S_{i}^{\prime}$ when referring to it with respect to the lattice $N_{i}^{\prime}$. This choice of lattice will allow us to prove Lemma 4.2, which simplifies the considerations in Section 5. In particular, it will yield a convenient explicit description of $\left(S_{i}^{\prime}\right)^{*}$ (see Lemma 5.1).

Set $q:=|\mathcal{V}|$ and $q_{i}:=\left|\mathcal{V}_{i}\right|$ for $i=1, \ldots, t$. We define $\Psi$ to be the map

$$
\begin{aligned}
& \Psi:(\operatorname{ker} \varphi)^{\perp} \rightarrow \bigoplus_{v \in \mathcal{V}} \mathbb{Z} \cong \mathbb{Z}^{q} \\
&\left(y_{1}, \ldots, y_{t}\right) \mapsto\left(\left\langle y_{i_{v}}, e_{i_{v}, v}\right\rangle\right)_{v \in \mathcal{V}}
\end{aligned}
$$

where for each $v, i_{v}$ is any index such that $v \in \mathcal{V}_{i_{v}}$. Since $\left\langle y_{i_{1}}, e_{i_{1}, v}\right\rangle=\left\langle y_{i_{2}}, e_{i_{2}, v}\right\rangle$ whenever $v \in \mathcal{V}_{i_{1}} \cap \mathcal{V}_{i_{2}}$, $\Psi$ is a well-defined map. In an analogous fashion to the definition of $\Psi$, for each $i \in\{1, \ldots, t\}$, we define the map

$$
\begin{aligned}
\Psi_{i}: M_{i}^{\prime} & \rightarrow \bigoplus_{v \in \mathcal{V}_{i}} \mathbb{Z} \cong \mathbb{Z}^{q_{i}} \\
y & \mapsto\left(\left\langle y, e_{i, v}\right\rangle\right)_{v \in \mathcal{V}_{i}} .
\end{aligned}
$$

Lemma 4.2. The maps $\Psi, \Psi_{1}, \ldots, \Psi_{t}$ are surjective.
Proof. Let $\left\{\epsilon_{i, v}\right\}_{v \in \mathcal{V}_{i}}$ be the standard basis of $\bigoplus_{v \in \mathcal{V}_{i}} \mathbb{Z}$ and $\left\{e_{i, v}^{*}\right\}_{v \in \widehat{\mathcal{V}}_{i}}$ the lattice basis of $M_{i}^{\prime}$ dual to the lattice basis $\left\{e_{i, v}\right\}_{v \in \hat{\mathcal{V}}_{i}}$ of $N_{i}^{\prime}$. The maps $\Psi_{i}$ are surjective, since each element $e_{i, v}^{*}$ is mapped into $\epsilon_{i, v}$, for $v \in \mathcal{V}_{i}$.

We now prove that $\Psi$ is surjective. Since the codomains of the maps $\Psi_{i}$ span the codomain of $\Psi$, it is enough to check that for each $i \in\{1, \ldots, t\}$ and for each $v \in \mathcal{V}_{i}$, there exists an element $\left(y_{1}, \ldots, y_{t}\right) \in(\operatorname{ker} \varphi)^{\perp} \subset M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime}$ such that $y_{i}=e_{i, v}^{*}$. This is true since it suffices to choose $\left(y_{1}, \ldots, y_{t}\right)$ as

$$
\sum_{i \text { such that } v \in V_{i}} e_{i, v}^{*} \in\left(M_{1}^{\prime} \oplus \cdots \oplus M_{t}^{\prime}\right) \cap\left(\operatorname{ker} \varphi_{\mathbb{R}}\right)^{\perp}=(\operatorname{ker} \varphi)^{\perp} .
$$

As a consequence of Lemma 4.2, the extensions of $\Psi, \Psi_{1}, \ldots, \Psi_{t}$ to the real vector space maps

$$
\Psi_{\mathbb{R}},\left(\Psi_{1}\right)_{\mathbb{R}}, \ldots,\left(\Psi_{t}\right)_{\mathbb{R}}
$$

are linear surjective maps. We define natural projections

$$
p_{i}: \bigoplus_{v \in \mathcal{V}} \mathbb{R} \rightarrow \bigoplus_{v \in \mathcal{V}_{i}} \mathbb{R}
$$

as the identity over $\bigoplus_{v \in \mathcal{V}_{i}} \mathbb{R}$ and the zero map over $\bigoplus_{v \in \mathcal{V} \backslash \mathcal{V}_{i}} \mathbb{R}$.

Let $\mathcal{D}$ be the set of parameters

$$
\mathcal{D}:=\Psi_{\mathbb{R}}\left(\varphi_{\mathbb{R}}^{*}\left(P^{*}\right)\right) \subset \bigoplus_{v \in \mathcal{V}} \mathbb{R}
$$

Given a point $\lambda=\left(\lambda_{v}\right)_{v \in \mathcal{V}} \in \mathcal{D}$, define the fibre

$$
H_{i, \lambda}:=\left(\Psi_{i}\right)_{\mathbb{R}}^{-1}\left(p_{i}(\lambda)\right) \cap\left(S_{i}^{\prime}\right)^{*}=\left\{y \in\left(S_{i}^{\prime}\right)^{*}:\langle y, v\rangle=\lambda_{v} \text { for all } v \in \mathcal{V}_{i}\right\} \subset\left(M_{i}^{\prime}\right)_{\mathbb{R}} .
$$

Denote by $F_{i}^{*}$ the $\left(d_{i}-q_{i}\right)$-dimensional face of $\left(S_{i}^{\prime}\right)^{*}$ given by

$$
\begin{equation*}
F_{i}^{*}:=H_{i,(-1, \ldots,-1)} . \tag{4.4}
\end{equation*}
$$

From equation (4.3), we obtain the desired decomposition of $P^{*}$ :

$$
\begin{align*}
P^{*} & \cong \bigsqcup_{\left(\lambda_{v}\right)_{v \in \mathcal{V} \in \mathcal{D}}}\left\{\left(y_{1}, \ldots, y_{t}\right) \in\left(S_{1}^{\prime}\right)^{*} \times \cdots \times\left(S_{t}^{\prime}\right)^{*}:\left\langle y_{i}, e_{i, v}\right\rangle=\lambda_{v} \text { for all } v \in \mathcal{V}_{i}, i=1, \ldots, t\right\}  \tag{4.5}\\
& =\bigsqcup_{\lambda \in \mathcal{D}} H_{1, \lambda} \times \cdots \times H_{t, \lambda} .
\end{align*}
$$

In other words, $P^{*}$ is sliced into a disjoint union of sections (see Figure 2).

## 5. Bounding the volume of $P^{*}$ via integration

In this section, we apply equation (4.5) to obtain a finer bound on the volume of $P^{*}$ in the case when $P$ decomposes into just two simplices. From here onward, we assume we are in the setup of Corollary 2.3 with $t=2$ : that is, $P$ decomposes in two minimal canonical simplices $S_{1}$ and $S_{2}$ of dimensions $d_{1}$ and $d_{2}$, respectively. As $P$ is not a simplex, clearly this decomposition is irredundant, so the results of Section 4.2 apply. We will continue to use the notation introduced in Section 4, in particular the choice of $N_{i}^{\prime}, N, S_{i}^{\prime}$ in Section 4.2. Note that $q=r_{2}=r=|\mathcal{V}|=\left|\mathcal{V}_{1}\right|=\left|\mathcal{V}_{2}\right|$ is the number of common vertices of $S_{1}$ and $S_{2}$.

The equality in equation (4.5) and Lemma 4.2 allow us to calculate the volume $\operatorname{vol}_{M}\left(P^{*}\right)$ by integrating the sections over the possible values of $\lambda$. In particular,

$$
\begin{equation*}
\operatorname{vol}_{M}\left(P^{*}\right)=\int_{\lambda \in \mathcal{D}} \operatorname{vol}_{M_{1}^{\prime}}\left(H_{1, \lambda}\right) \operatorname{vol}_{M_{2}^{\prime}}\left(H_{2, \lambda}\right) d \lambda . \tag{5.1}
\end{equation*}
$$

Before attempting to bound such a value, we present an alternative description of $\mathcal{D}$. For $i=1,2$, we define $\mathcal{D}_{i}$ as

$$
\mathcal{D}_{i}:=\left(\Psi_{i}\right)_{\mathbb{R}}\left(\left(S_{i}^{\prime}\right)^{*}\right),
$$

and we note that (since the maps $p_{i}$ defined in the previous section correspond to the identity maps here)

$$
\begin{equation*}
\mathcal{D}=\mathcal{D}_{1} \cap \mathcal{D}_{2} \tag{5.2}
\end{equation*}
$$

Recall that a lattice basis $\left\{e_{i, v}\right\}$ for $N_{i}^{\prime}$ is given by the elements of $\widehat{\mathcal{V}}_{i}=\operatorname{vert}\left(S_{i}\right) \backslash\left\{v_{i}\right\}$. Denote by $\left(\beta_{i, v}\right)_{v \in \operatorname{vert}\left(S_{i}\right)}$ the barycentric coordinates of the origin in the simplex $S_{i}$ : that is, $\sum_{v \in \operatorname{vert}\left(S_{i}\right)} \beta_{i, v} v=\mathbf{0}$, where $\sum_{v \in \operatorname{vert}\left(S_{i}\right)} \beta_{i, v}=1$. Note that $\beta_{i, v}>0$ for any $v \in \operatorname{vert}\left(S_{i}\right)$. Hence we can express $v_{i}$ as

$$
v_{i}=-\sum_{v \in \hat{\mathcal{V}}_{i}} \frac{\beta_{i, v}}{\beta_{i, v_{i}}} e_{i, v} .
$$

Let us denote by $\left\{\epsilon_{i, v}\right\}_{\nu \in \mathcal{V}_{i}}$ the standard basis of $\bigoplus_{\nu \in \mathcal{V}_{i}} \mathbb{Z}$. Lemma 5.1 below gives an explicit description for $\left(S_{i}^{\prime}\right)^{*}$ and $\mathcal{D}_{i}$ in terms of our chosen lattice bases. We omit the straightforward proof.
Lemma 5.1. With notation as above, for $i=1,2$,

$$
\begin{aligned}
\left(S_{i}^{\prime}\right)^{*} & =\operatorname{conv}\left(\left\{-\sum_{v \in \mathcal{V}} e_{i, v}^{*}\right\} \cup\left\{\left(\frac{1}{\beta_{i, w}}-1\right) e_{i, w}^{*}-\sum_{v \in \mathcal{V} \backslash\{w\}} e_{i, v}^{*}\right\}_{w \in \widehat{\mathcal{V}}_{i}}\right), \\
\mathcal{D}_{i} & =\operatorname{conv}\left(\left\{-\sum_{v \in \mathcal{V}} \epsilon_{i, v}^{*}\right\} \cup\left\{\left(\frac{1}{\beta_{i, w}}-1\right) \epsilon_{i, w}^{*}-\sum_{v \in \mathcal{V} \backslash\{w\}} \epsilon_{i, v}^{*}\right\}_{w \in \mathcal{V}}\right)
\end{aligned}
$$

By using the inequality $f_{1} f_{2} \leq \frac{f_{1}^{2}+f_{2}^{2}}{2}$, we can bound equation (5.1) via

$$
\begin{align*}
\operatorname{vol}_{M}\left(P^{*}\right) & \leq \int_{\lambda \in \mathcal{D}} \frac{\operatorname{vol}_{M_{1}^{\prime}}\left(H_{1, \lambda}\right)^{2}+\operatorname{vol}_{M_{2}^{\prime}}\left(H_{2, \lambda}\right)^{2}}{2} d \lambda \\
& =\frac{1}{2} \int_{\lambda \in \mathcal{D}} \operatorname{vol}_{M_{1}^{\prime}}\left(H_{1, \lambda}\right)^{2} d \lambda+\frac{1}{2} \int_{\lambda \in \mathcal{D}} \operatorname{vol}_{M_{2}^{\prime}}\left(H_{2, \lambda}\right)^{2} d \lambda  \tag{5.3}\\
& \leq \frac{1}{2} \int_{\lambda \in \mathcal{D}_{1}} \operatorname{vol}_{M_{1}^{\prime}}\left(H_{1, \lambda}\right)^{2} d \lambda+\frac{1}{2} \int_{\lambda \in \mathcal{D}_{2}} \operatorname{vol}_{M_{2}^{\prime}}\left(H_{2, \lambda}\right)^{2} d \lambda
\end{align*}
$$

where the final inequality follows from equation (5.2). It is convenient to perform a change of variables for $i=1,2$ via the maps

$$
\alpha=\left(\alpha_{v}\right)_{v \in \mathcal{V}} \stackrel{f_{i}}{\mapsto}\left(\frac{1}{\beta_{i, v}} \alpha_{v}-1\right)_{v \in \mathcal{V}} .
$$

By Lemma 5.1, the integration domain $\mathcal{D}_{i}$ becomes the unimodular $q$-dimensional simplex $\Delta_{(q)}$ : that is, the convex hull of the origin and the standard basis of $\mathbb{Z}^{q}$. Hence equation (5.3) can be rewritten as

$$
\begin{equation*}
\operatorname{vol}_{M}\left(P^{*}\right) \leq \frac{1}{2} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{1, v}} \int_{\alpha \in \Delta_{(q)}} \operatorname{vol}_{M_{1}^{\prime}}\left(H_{1, f_{i}(\alpha)}\right)^{2} d \boldsymbol{\alpha}+\frac{1}{2} \prod_{\nu \in \mathcal{V}} \frac{1}{\beta_{2, v}} \int_{\boldsymbol{\alpha} \in \Delta_{(q)}} \operatorname{vol}_{M_{2}^{\prime}}\left(H_{2, f_{2}(\boldsymbol{\alpha})}\right)^{2} d \boldsymbol{\alpha} \tag{5.4}
\end{equation*}
$$

Lemma 5.2 [2, Lemma 3.5 III]. With notation as above, for $i=1,2$,

$$
\operatorname{vol}_{M_{i}^{\prime}}\left(H_{i, f_{i}(\alpha)}\right)=\operatorname{vol}_{M_{i}^{\prime}}\left(F_{i}^{*}\right)\left(1-\sum_{v \in \mathcal{V}_{i}} \alpha_{v}\right)^{d_{i}-q}
$$

where $F_{i}$ is the $\left(d_{i}-q\right)$-dimensional face of $\left(S_{i}^{\prime}\right)^{*}$ defined in equation (4.4).
The inequality in equation (5.4) can now be rewritten as

$$
\begin{align*}
\operatorname{vol}_{M}\left(P^{*}\right) \leq & \frac{1}{2} \prod_{\nu \in \mathcal{V}} \frac{1}{\beta_{1, v}} \operatorname{vol}_{M_{1}^{\prime}}\left(F_{1}^{*}\right)^{t} \int_{\boldsymbol{\alpha} \in \Delta_{(q)}}\left(1-\sum_{v \in \mathcal{V}} \alpha_{v}\right)^{2\left(d_{1}-q\right)} d \boldsymbol{\alpha} \\
& +\frac{1}{2} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{2, v}} \operatorname{vol}_{M_{2}^{\prime}}\left(F_{2}^{*}\right)^{t} \int_{\boldsymbol{\alpha} \in \Delta_{(q)}}\left(1-\sum_{v \in \mathcal{V}} \alpha_{v}\right)^{2\left(d_{2}-q\right)} d \boldsymbol{\alpha} \tag{5.5}
\end{align*}
$$

The following lemma derives from a special case of a well-known representation of the beta function (see, for example, [6, Representation 4.3-2]).

## Lemma 5.3.

$$
\int_{\boldsymbol{\alpha} \in \Delta_{(a)}}\left(1-\alpha_{1}-\ldots-\alpha_{a}\right)^{b} d \boldsymbol{\alpha}=\frac{b!}{(a+b)!}
$$

Applying Lemma 5.3 to equation (5.5) yields

$$
\begin{equation*}
\operatorname{vol}_{M}\left(P^{*}\right) \leq \frac{1}{2} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{1, v}} \operatorname{vol}_{M_{1}^{\prime}}\left(F_{1}^{*}\right)^{2} \frac{\left(2\left(d_{1}-q\right)\right)!}{\left(q+2\left(d_{1}-q\right)\right)!}+\frac{1}{2} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{2, v}} \operatorname{vol}_{M_{2}^{\prime}}\left(F_{2}^{*}\right)^{2} \frac{\left(2\left(d_{2}-q\right)\right)!}{\left(q+\left(2\left(d_{2}-q\right)\right)!\right.} . \tag{5.6}
\end{equation*}
$$

The volume of $F_{i}^{*}$ is computed in Lemma 5.4 below. Its proof is omitted since it is a straightforward consequence of the description of $\left(S_{i}^{\prime}\right)^{*}$ given in Lemma 5.1.

Lemma 5.4. With notation as above, for $i=1,2$,

$$
\operatorname{vol}_{M_{i}^{\prime}}^{( }\left(F_{i}^{*}\right)=\frac{1}{\left(d_{i}-q\right)!} \prod_{v \in \widehat{\mathcal{V}}_{i} \backslash \mathcal{V}} \frac{1}{\beta_{i, v}}
$$

Finally, applying Lemma 5.4 to equation (5.6) gives the following bound for $\operatorname{vol}_{M}\left(P^{*}\right)$ :

$$
\begin{align*}
& \operatorname{vol}_{M}\left(P^{*}\right) \leq \frac{1}{2}  \tag{5.7}\\
& \frac{\left(2\left(d_{1}-q\right)\right)!}{\left(q+2\left(d_{1}-q\right)\right)!\left(\left(d_{1}-q\right)!\right)^{2}} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{1, v}} \prod_{v \in \widehat{\mathcal{V}}_{1} \backslash \mathcal{V}} \frac{1}{\beta_{1, v}^{2}} \\
&+\frac{1}{2} \frac{\left(2\left(d_{2}-q\right)\right)!}{\left(q+2\left(d_{2}-q\right)\right)!\left(\left(d_{2}-q\right)!\right)^{2}} \prod_{v \in \mathcal{V}} \frac{1}{\beta_{2, v}} \prod_{v \in \widehat{\mathcal{V}}_{2} \backslash \mathcal{V}} \frac{1}{\beta_{2, v}^{2}} .
\end{align*}
$$

## 6. Final cases

In this final section, we address the remaining cases of Corollary 3.1. That is, we prove that the decompositions

1. $t=2, d_{1}=d_{2}=d-1$, for $d \geq 4$
2. $t=2, d_{1}=d-1, d_{2}=d-2, d \in\{4,5\}$
3. $t=3, d_{1}=d_{2}=d_{3}=d-2, d \in\{4,5\}$
satisfy Theorem 1.1.
6.1. The case $t=2, d_{1}=d_{2}=d-1$

By equation (2.1), we have $q=d-2$. Hence the inequality in equation (5.7) can be rewritten as

$$
\begin{equation*}
\operatorname{vol}_{M}\left(P^{*}\right) \leq \frac{1}{d!}\left(\prod_{v \in \mathcal{V}} \frac{1}{\beta_{1, v}} \prod_{v \in \widehat{\mathcal{V}}_{1} \backslash \mathcal{V}} \frac{1}{\beta_{1, v}^{2}}+\prod_{v \in \mathcal{V}} \frac{1}{\beta_{2, v}} \prod_{v \in \widehat{\mathcal{V}}_{2} \backslash \mathcal{V}} \frac{1}{\beta_{2, v}^{2}}\right) . \tag{6.1}
\end{equation*}
$$

We focus on the product

$$
\prod_{\nu \in \mathcal{V}} \frac{1}{\beta_{i, v}} \prod_{\nu \in \widehat{\mathcal{V}}_{i} \backslash \mathcal{V}} \frac{1}{\beta_{i, v}^{2}}
$$

for each $i=1,2$. Note that in Section 4.2, we chose to exclude one of the vertices (called $v_{i}$ ) of vert $\left(S_{i}\right) \backslash \mathcal{V}$ from appearing in $\widehat{\mathcal{V}}_{i}$. As there are two such vertices (say, vert $\left.\left(S_{i}\right) \backslash \mathcal{V}=\left\{v_{i}, u_{i}\right\}\right)$, we can exclude the
one whose corresponding barycentric coordinate is smaller: that is, $\beta_{i, v_{i}} \leq \beta_{i, u_{i}}$. This yields

$$
\begin{equation*}
\prod_{v \in \mathcal{V}} \frac{1}{\beta_{i, v}} \prod_{v \in \widehat{\mathcal{V}}_{i} \backslash \mathcal{V}} \frac{1}{\beta_{i, v}^{2}}=\left(\prod_{v \in \mathcal{V}} \frac{1}{\beta_{i, v}}\right) \frac{1}{\beta_{i, u_{i}}^{2}} \leq\left(\prod_{v \in \mathcal{V}} \frac{1}{\beta_{i, v}}\right) \frac{1}{\beta_{i, u_{i}}} \frac{1}{\beta_{i, v_{i}}}=\frac{1}{\beta_{i, 0} \cdots \beta_{i, d-1}}, \tag{6.2}
\end{equation*}
$$

where $\left\{\beta_{i, v}: v \in \operatorname{vert}\left(S_{i}\right)\right\}=\left\{\beta_{i, j}: j=0, \ldots, d-1\right\}$. Notice that the equality in equation (6.2) is attained if and only if $\beta_{i, u_{i}}=\beta_{i, v_{i}}$.

For each $i=1$, 2 , let us order the barycentric coordinates such that $\beta_{i, 0} \geq \beta_{i, 1} \geq \cdots \geq \beta_{i, d-1}$.
Lemma 6.1 [3, Lemma 4.2(d)]. With notation as above,

$$
\frac{1}{\beta_{i, 0} \cdots \beta_{i, d-1}} \leq\left(s_{d}-1\right)^{2},
$$

with equality if and only if

$$
\begin{equation*}
\left(\beta_{i, 0}, \ldots, \beta_{i, d-1}\right)=\left(\frac{1}{s_{1}}, \ldots, \frac{1}{s_{d-1}}, \frac{1}{s_{d}-1}\right) \tag{6.3}
\end{equation*}
$$

Applying Lemma 6.1 and equations (6.2)-(6.1), we obtain

$$
\operatorname{vol}_{M}\left(P^{*}\right)<\frac{2\left(s_{d}-1\right)^{2}}{d!}
$$

This inequality is strict, since the condition that $\beta_{i, u_{i}}=\beta_{i, v_{i}}$ from equation (6.2) and the condition in equation (6.3) from Lemma 6.1 cannot hold simultaneously.

### 6.2. The cases $t=2, d_{1}=d-1, d_{2}=d-2, d \in\{4,5\}$

The barycentric coordinates of the canonical Fano simplices up to and including dimension four are classified in [11]. Hence we can verify that in this situation, the right-hand side of equation (5.7) is always strictly less than $2\left(s_{d}-1\right)^{2} / d$ !.
6.3. The cases $t=3, d_{1}=d_{2}=d_{3}=d-2, d \in\{4,5\}$

Corollary 2.3 implies that $r_{2}=r_{3}=d-3$. To prove the inequality in these final cases, we explicitly construct every minimal polytope $P$ of dimension four or five that admits a decomposition into three minimal simplices of dimensions two or three, respectively, such that the vertices of $P$ generate the ambient lattice $N$. Under this setting, we note that $P$ is uniquely determined by

1. the barycentric coordinates of the simplices $S_{1}, S_{2}, S_{3}$ in the decomposition; and
2. the choice of $d-3$ vertices in common with $S_{2}$ and $S_{1}$, together with the choice of $d-3$ vertices in common with $S_{3}$ and $S_{1} \cup S_{2}$.

This follows from the following general construction. The (reduced) weights of a canonical Fano simplex $S$ of dimension $n$ are the positive integers $\left(k \beta_{0}, \ldots, k \beta_{n}\right)$ given by the barycentric coordinates $\left(\beta_{0}, \ldots, \beta_{n}\right)$ of the origin (with respect to the vertices of $S$ ), where $k$ is the smallest positive integer such that the $k \beta_{i}$ are all integral. In particular, the weights of a canonical Fano simplex are coprime. Moreover, since the vertices of a canonical Fano simplex are primitive lattice points, the weights are well-formed: that is, any $n$ of them are coprime. Let us use the fact that any minimal polytope $P$ has a decomposition into $t$ minimal simplices. We proceed invariantly since we do not know the embedding of these simplices into the lattice $N$. Let $\underline{\lambda}^{(n)}=\left(\lambda_{0}, \ldots, \lambda_{n}\right)$ denote the (reduced, well-formed) weights of a minimal canonical Fano simplex of dimension $n$. Fix weights $\underline{\lambda}^{\left(d_{1}\right)}, \ldots, \underline{\lambda}^{\left(d_{t}\right)}$. For each pair $(i, j)$ with $1 \leq i<j \leq t$, we pick a (possibly empty) subset $V_{i j} \subset\left\{0, \ldots, d_{i}\right\} \times\left\{0, \ldots, d_{j}\right\}$ such

Table 1. The weights of the minimal canonical Fano simplices in dimension three.

| $(1,1,1,1)$ | $(1,1,1,2)$ | $(1,1,1,3)$ | $(1,1,2,2)$ | $(1,1,2,3)$ |
| :--- | :--- | :--- | :--- | :--- |
| $(1,1,2,4)$ | $(1,1,3,4)$ | $(1,1,3,5)$ | $(1,1,4,6)$ | $(1,2,3,5)$ |
| $(1,3,4,5)$ | $(2,3,5,7)$ | $(3,4,5,7)$ |  |  |

that $V_{i j}: \pi_{1}\left(V_{i j}\right) \rightarrow \pi_{2}\left(V_{i j}\right)$ is a bijection (here $\pi_{k}$ denotes the projection on the $k$ th factor). Let $\iota_{j}: \mathbb{Z}^{d_{j}+1} \rightarrow \bigoplus_{i=1}^{t} \mathbb{Z}^{d_{i}+1}, 1 \leq j \leq t$, be the natural inclusion on the $j$ th factor. Define

$$
\begin{aligned}
W & :=\left\langle\iota_{i}\left(\underline{\lambda}^{\left(d_{i}\right)}\right) \mid 1 \leq i \leq d\right\rangle, \\
V & :=\left\langle\iota_{i}\left(e_{\pi_{1}(v)}\right)-\iota_{j}\left(e_{\pi_{2}(v)}\right) \mid v \in V_{i j}, 1 \leq i<j \leq t\right\rangle .
\end{aligned}
$$

Applying $-\otimes \mathbb{R}$ ensures torsion-freeness of the quotient $\left(\bigoplus_{i=1}^{t} \mathbb{Z}^{d_{i}+1}\right) /(W+V)$, and therefore we get the exact sequence

$$
0 \rightarrow(W+V) \otimes \mathbb{R} \rightarrow\left(\bigoplus_{i=1}^{t} \mathbb{Z}^{d_{i}+1}\right) \otimes \mathbb{R} \xrightarrow{\varphi_{\mathbb{R}}} N \otimes \mathbb{R} \rightarrow 0,
$$

where $N$ is the lattice obtained as the quotient $\left(\bigoplus_{i=1}^{t} \mathbb{Z}^{d_{i}+1}\right) / K$, where $K$ is the direct summand defined by $\left(\bigoplus_{i=1}^{t} \mathbb{Z}^{d_{i}+1}\right) \cap((W+V) \otimes \mathbb{R})$. We now define

$$
Q:=\varphi_{\mathbb{R}}\left(\bigoplus_{i=1}^{t} \operatorname{conv}\left\{e_{0}, \ldots, e_{d_{i}}\right\}\right) \subset N \otimes \mathbb{R},
$$

which by construction is a polytope whose vertices generate its ambient lattice $N$. In general, $Q$ may not be a minimal polytope; however, if $P$ is a minimal lattice polytope of dimension $d$ whose vertices generate its ambient lattice, then there exists a choice of integers $t, d_{1}, \ldots, d_{t}$, weights $\underline{\lambda}^{\left(d_{1}\right)}, \ldots, \underline{\lambda}^{\left(d_{t}\right)}$ of minimal Fano simplices $S_{1}, \ldots, S_{t}$ of dimensions $d_{1}, \ldots, d_{t}$ and subsets $V_{i j}$ (for $1 \leq i<j \leq t$ ) such that the polytope $Q$ constructed above is equal to $P$. The fact that we can recover $P$ from the construction of $Q$ is a consequence of Lemma 4.1, while the existence of the parameters $t, d_{1}, \ldots, d_{t}$ and the weights follows from Corollary 2.3.

We now specialise this construction to the case $t=3, d_{1}=d_{2}=d_{3}=d-2$ for $d \in\{4,5\}$. The weights of the minimal canonical Fano simplices of dimensions two and three have been classified [10, Figure 1 and Proposition 4.3]. There are two possible weights in dimension two: ( $1,1,1$ ) and ( $1,1,2$ ). In dimension three, there are 13 possible weights, ${ }^{1}$ recorded in Table 1. Since the choices for the common vertices (encoded in the sets $V_{i j}, 1 \leq i<j \leq 3$ ) are finite, all the minimal canonical Fano polytopes $P$ admitting such a decomposition and whose vertices generate the ambient lattice $N$ can be classified.

We use the computer algebra system MaGma [5] to derive the classification. Source code and output can be downloaded from Zenodo [4]. In the first case ( $d_{1}=d_{2}=d_{3}=2$ ), there are exactly four such four-dimensional polytopes, and in each case, the inequality of Theorem 1.1 holds. To solve the second case ( $d_{1}=d_{2}=d_{3}=3$ ), we first build all possible four-dimensional minimal polytopes $P^{\prime}$ whose vertices generate the ambient lattice and admit a decomposition into two three-dimensional minimal canonical Fano simplices $S_{1}$ and $S_{2}$. We then verify that any five-dimensional polytope $P$ decomposing as $S_{1}, S_{2}$ and $S_{3}$ satisfies the inequality in equation (3.5) for each choice of three-dimensional minimal

[^0]canonical Fano simplex $S_{3}$; that is, we verify that
$$
\operatorname{Vol}\left(P^{*}\right) \leq \frac{7!}{4!3!} \operatorname{Vol}\left(P^{\prime *}\right) \cdot 2\left(s_{3}-1\right)^{2}<2\left(s_{5}-1\right)^{2}
$$
holds in each case. There are 147 minimal four-dimensional polytopes with a decomposition into two three-dimensional minimal canonical Fano simplices and whose vertices generate the lattice $N$, and in each case, the inequality holds. This completes the proof of Theorem 1.1.

### 6.4. Bounding the volume of $P$

Unfortunately, the methods used here to prove a sharp upper bound on the volume of $P^{*}$ do not immediately help provide an upper bound on the volume of $P$. Since there is no known decomposition result for maximal canonical Fano polytopes, we would again have to pass to the dual side and consider minimal 'canonical' subpolytopes of $P^{*}$. One could still decompose these into 'canonical' simplices. However, they would no longer be lattice simplices, and there are no known applicable bounds on the corresponding barycentric coordinates of the origin in the rational case.

Conflict of Interest. The authors have no conflict of interest to declare.
Financial support. GB was supported by the Stiftelsen GS Magnusons Fund and by a Jubileumsfond grant from the Knut and Alice Wallenbergs Foundation.
