Introduction

Sphenothallus Hall, 1847, one of the most widely distributed and longest ranging genera in the fossil record, has been documented from all systems of the Paleozoic Erathem except the Permian (Table 1), although it has been stated (e.g., Choi, 1990; Bolton, 1994; Fatka et al., 2012) that the genus also occurs in that system. At present the first appearance of this epibenthic, polypoid medusozoan cnidarian lies in Cambrian Stage 3, while the previously known youngest occurrences are in the Pennsylvanian System. *Sphenothallus* has been found in numerous formations on all continents except Australia and Antarctica. It occurs in a variety of marine facies ranging from shallow nearshore to deep offshore and has even been found in strata of coastal lacustrine origin, probably as an allochthonous element (Lerner and Lucas, 2011). Many of the rock units known to contain *Sphenothallus* also contain conulariids (Table 1), an extinct group of marine scyphozoans that may have been closely related to *Sphenothallus* (Van Iten et al., 1992, 1996). Van Iten et al. (1992) interpreted *Sphenothallus* as a medusozoan cnidarian of uncertain class-level affinities, but later Dzik et al. (2017) documented internal peridermal structures that may be homologous to similar features in the periderm of coronate scyphozoans (see for example illustrations in Van Iten, 1992, and Van Iten et al., 1996).

The present article describes multiple, very well-preserved specimens of *Sphenothallus carniolica* (Kolar-Jurkovšek and Jurkovšek, 1997) from limestone strata of early Late Triassic (late Carnian) age in the Julian Alps of northwest Slovenia. Some of these specimens were originally described under the name *Valvasoria carniolica* Kolar-Jurkovšek and Jurkovšek, 1997, which was interpreted as a tubiculous worm of possible nematode or sipunculid affinities (see also Hitij et al., 2019). Thus, this is the first report of *Sphenothallus* from the Mesozoic Erathem. Furthermore, *Sphenothallus* is now established as a long-ranging medusozoan cnidarian, which, together with conulariids, survived the End Permian Mass Extinction Event (MacLeod, 2013).

*Corresponding Author.

Geological setting

The studied *Sphenothallus* specimens were collected from thin, gray, laminated lime mudstones in the Kozja dnina Member of the Martuljek Limestone (early Late Triassic, late Carnian) in the northeast Julian Alps (Vrata Valley) of northwest Slovenia (Fig. 1). The late Carnian (Tuvalian) age of the section that yielded the specimens is based on conodont assemblages (*Quadralella polygnathiformis* Zone; Kolar-Jurkovšek, 1991). The section at Kozja dnina is ∼80 m thick and represents a deep water paleoenvironment (Bitner et al., 2010). The strata were deposited in an interplatform basin, where anoxic conditions and rapid sedimentation enabled exceptional preservation of both invertebrate and vertebrate fossils (Celarc and Kolar-Jurkovšek, 2008). In addition to *Sphenothallus*, the Kozja dnina limestones also contain bivalves, brachiopods, echinoids, crinoids, asteroids, ammonites, belemnites, scleractinian corals, shrimp, lobsters, thylacocephalans, and fishes (Hitij et al., 2019; Gašparič et al., 2020).

Material and methods

The present study is based on direct examination of 31 specimens of *Sphenothallus carniolica* (Kolar-Jurkovšek and Jurkovšek, 1997) from the Kozja dnina Member of the Martuljek Limestone. All specimens occur on exposed bedding planes, their preserved periderm appearing light to dark brown on the light gray weathered limestone, in some cases with a blueish hue resulting from vivianitization. Specimens were examined and photographed using reflected light and scanning electron microscopy (secondary electron mode). Material photographed under reflected light was whitened with ammonium chloride sublimate. Photographs were taken with a millimetric scale bar using a Nikon Z 6II digital camera equipped with a NIKKOR Z MC 105mm f/2.8 VR S lens. Photographs were edited in Photoshop CS6, and figures containing light photographs were assembled in CorelDRAW X8. Scanning electron microscopy was conducted using a JEOL JSM-649OLV. Finally, the elemental composition of the periderm of one of the specimens (T-1287) was determined using an Oxford INCA Energy 350 EDS under the following operating conditions: chamber vacuum

Table 1. Selected documented occurrences of *Sphenothallus* Hall, 1847, in the Phanerozoic rock record. Asterisk next to a formation or member name indicates that the unit also yields conulariids.

Systematic paleontology

Phylum Cnidaria Verrill, 1865
Subphylum Medusozoa Peterson, 1979
Class, Order, Family uncertain
Genus *Sphenothallus* Hall, 1847

Type species.—*Sphenothallus angustifolius* Hall, 1847, originally described from the Upper Ordovician of eastern New York State, USA.

Sphenothallus carniolica (Kolar-Jurkovšek and Jurkovšek, 1997)
Figures 3–5

1997 *Valvasoria carniolica* Kolar-Jurkovšek and Jurkovšek, p. 1, pl. 1, figs. 1–4.
2019 *Valvasoria carniolica*; Hitij et al., p. 21, figs. 16, 17.

Holotype.—BJ1286 (originally designated as the holotype of *Valvasoria carniolica* Kolar-Jurkovšek and Jurkovšek, 1997; currently reposited in the collection of Bogdan Jurkovšek).

Paratypes.—BJ1287, BJ1419 (originally designated as paratypes of *Valvasoria carniolica*; currently reposited in the collection of Bogdan Jurkovšek).

Diagnosis.—Peridermal tube very gently tapered (angle of expansion mostly <2°), non-branching, lacking regular transverse annulations.

Occurrence.—Thin, gray, laminated lime mudstones in the Kozja dnina Member of the Martuljek Limestone (early Late Triassic, late Carnian, Tuvalian; *Paragondolella polygnathiformis* conodont Zone) in the Vrata Valley in the northeast Julian Alps, northwest Slovenia. The geographic coordinates of the fossil locality are Lat. 46°24′08.1″N, Long. 13°50′46.2″E.

Figure 1. Simplified geographical map of northwest Slovenia. The location of Kozja dnina in the Vrata Valley is marked by a star (figure adapted from Bitner et al., 2010).

Description.—Partial to nearly complete, compressed specimens lying parallel to bedding and ranging up to 129.5 mm in length and 5.5 mm in width. Specimens consist of one or more portions of the slender, originally sub-elliptical (transversely) main tube or of nearly the entire periderm, including the sub-conical attachment disc, although without the basal membrane. Attachment disc measures up to ∼3.1 mm in diameter. Apertural margin not preserved; terminal schott (apical wall) absent. Main tube very gently tapered (mostly <2°) in the plane of the well-developed pair of oppositely situated, longitudinal thickenings, variably curved parallel to bedding, in some cases with the degree of curvature increasing toward the apical end. Relatively thin periderm between the longitudinal thickenings missing or, where present, exhibiting coarse, irregular, transverse to oblique wrinkles. Regular transverse annulations absent. Longitudinal thickenings terminate or thin near the apertural end of the main tube. Skeletal material phosphatic, very finely lamellar, light to dark brown or dark bluish gray, with exfoliated lamellae in some specimens exhibiting possible "plywood [micro]structure" (Vinn and Mironenko, 2021). Some specimens exhibit minute, shallow, sub-circular to sub-elliptical pores or pits ranging from ∼2–4 μm in diameter.

Additional material.—BJ2505 (currently reposited in the collection of Bogdan Jurkovšek); T-1256, T-1257, T-1270–T-1287 (currently reposited in the collection of Tomaž Hitij and Jure Žalohar).

Remarks.—The principal diagnostic feature of *Sphenothallus*, namely the pair of longitudinal thickenings situated at the end points of the major diameter of the subelliptical main tube, is

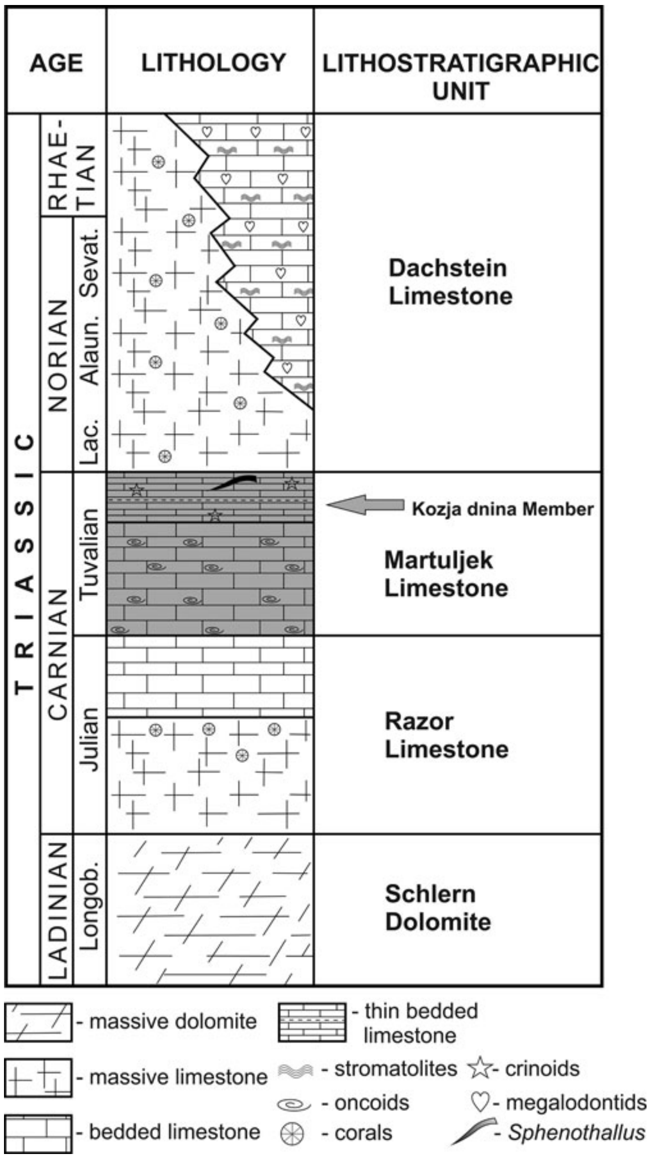

Figure 2. Lithostratigraphy of the Tuvalian section with platy limestones yielding *Sphenothallus carniolica* (Kolar-Jurkovšek and Jurkovšek, 1997) (arrow) at Kozja dnina (figure adapted from Celarc and Kolar-Jurkovšek, 2008). Norian stage subdivisions are abbreviated as: Lac. = Lacian; Alaun. = Alaunian; Sevat. = Sevatian.

well developed in the Slovenian material (Figs. 3.1–3.3, 3.5, 4.1–4.3, 5.1–5.4, 5.8). As in *Sphenothallus* from Paleozoic formations, compression of the Slovenian specimens perpendicular to bedding has caused the longitudinal thickenings to form berm-like elevations rising above the thinner, deformed skeletal wall between them, which in some cases (Fig. 5.8) is now absent. Also well displayed in the Slovenian material is the characteristic, parallel lamellar microstructure (Figs. 4.8, 5.5, 5.6), which is commonly exfoliated. Lamellae in one specimen appear to exhibit "plywood [micro]structure" (Fig. 5.5, 5.6), discovered by Vinn and Mironenko (2021, fig. 2C, D) in material from the Upper Mississippian of central Russia. A somewhat similar microstructure is present in the medusozoan *Torellella* Holm, 1893, from the upper Cambrian of Estonia (Vinn, 2006, 2022). The presence of calcium phosphate (apatite), which constitutes the bulk of most Paleozoic specimens, is corroborated both by the brown to blue-gray color of the specimens and by the results of EDS analysis (Fig. 6), which yielded strong spectral peaks for Ca and P.

Turning to other characters, the very low rate of taper of the main tube of the Slovenian specimens is similar to that of *S. angustifolius* from the Upper Ordovician of Ontario and Quebec, Canada (see for example Bolton, 1994, pls. 1.1–1.3) and *S. sica* Clarke, 1913, from the Lower Devonian Ponta Grossa Shale of Brazil (see for example Van Iten et al., 2019, fig. 4). The size of the attachment disc (Figs. 3.1, 3.2, 3.4, 3.5, 4.1–4.4, 4.6, 4.7, 5.1, 5.2), both absolute and in proportion to the size of the main tube, matches closely that of the attachment disc of *Sphenothallus* sp. from the Bear Gulch Member of the Upper Mississippian Heath Formation of Montana, western USA (see Van Iten et al., 1992, fig. 1). Interestingly, specimens preserving both the attachment disc and the long slender tube above it may be attached to hard biological substrates (see for example Van Iten et al., 2019, fig. 6), or, like the Slovenian specimens and the Bear Gulch material referred to in the preceding sentence, they may be unattached, suggesting that their original substrate may have been plant or other organic matter susceptible to rapid decay. Finally, smooth curvature of the main tube, with the degree of curvature commonly decreasing in the direction of the apertural end (Figs. 3.2, 4.1, 4.2, 4.6, 5.3, 5.4, 5.6), is a feature exhibited by many Paleozoic specimens (see for example Van Iten et al., 1996, pl. 2.1), as are thinning of the longitudinal thickenings in the vicinity of the aperture (Figs. 3.1, 3.3, 5.4) and the absence of well-defined annulation or other ornament (Fig. 4.5).

A noteworthy additional feature, previously documented in *Sphenothallus* cf. *S. angustifolius* from the Upper Mississippian of central Russia (Vinn and Mironenko, 2021, fig. 2f), is the presence in the main tube of some of the Slovenian specimens of microscopic, sub-circular to sub-elliptical pores or pits (Fig. 5.7), originally detected in specimen BJ1287 by Kolar-Jurkovšek and Jurkovšek (1997, figs. 2, 3). These shallow perforations are similar in size, shape, areal density, and pattern of distribution to the microscopic circular pores, or micropores, of conulariids (see Van Iten et al., 2005, 2006a, b, 2022, and references cited therein). Conulariid micropores have been compared with microscopic borings and bioclaustrations, and they have been interpreted as primary anatomical features. If the latter hypothesis is true, then the presence of these features in conulariids and *Sphenothallus* may provide additional support for the hypothesis (e.g., Van Iten et al., 1996) that the skeletons of these two taxa are mutually homologous.

Concluding remarks

Sphenothallus Hall, 1847, an extinct genus of medusozoan cnidarians, is now known from the lower Upper Triassic of northwest Slovenia (Julian Alps). Moreover, the well-preserved specimens of *S. carniolica* from Slovenia are the only documented representatives of the genus from the Mesozoic Erathem. The present discovery extends the known age range of *Sphenothallus* by ca. 80 million years, from the Kazimovian to the late Carnian, and thus across the critical Permian-Triassic boundary.

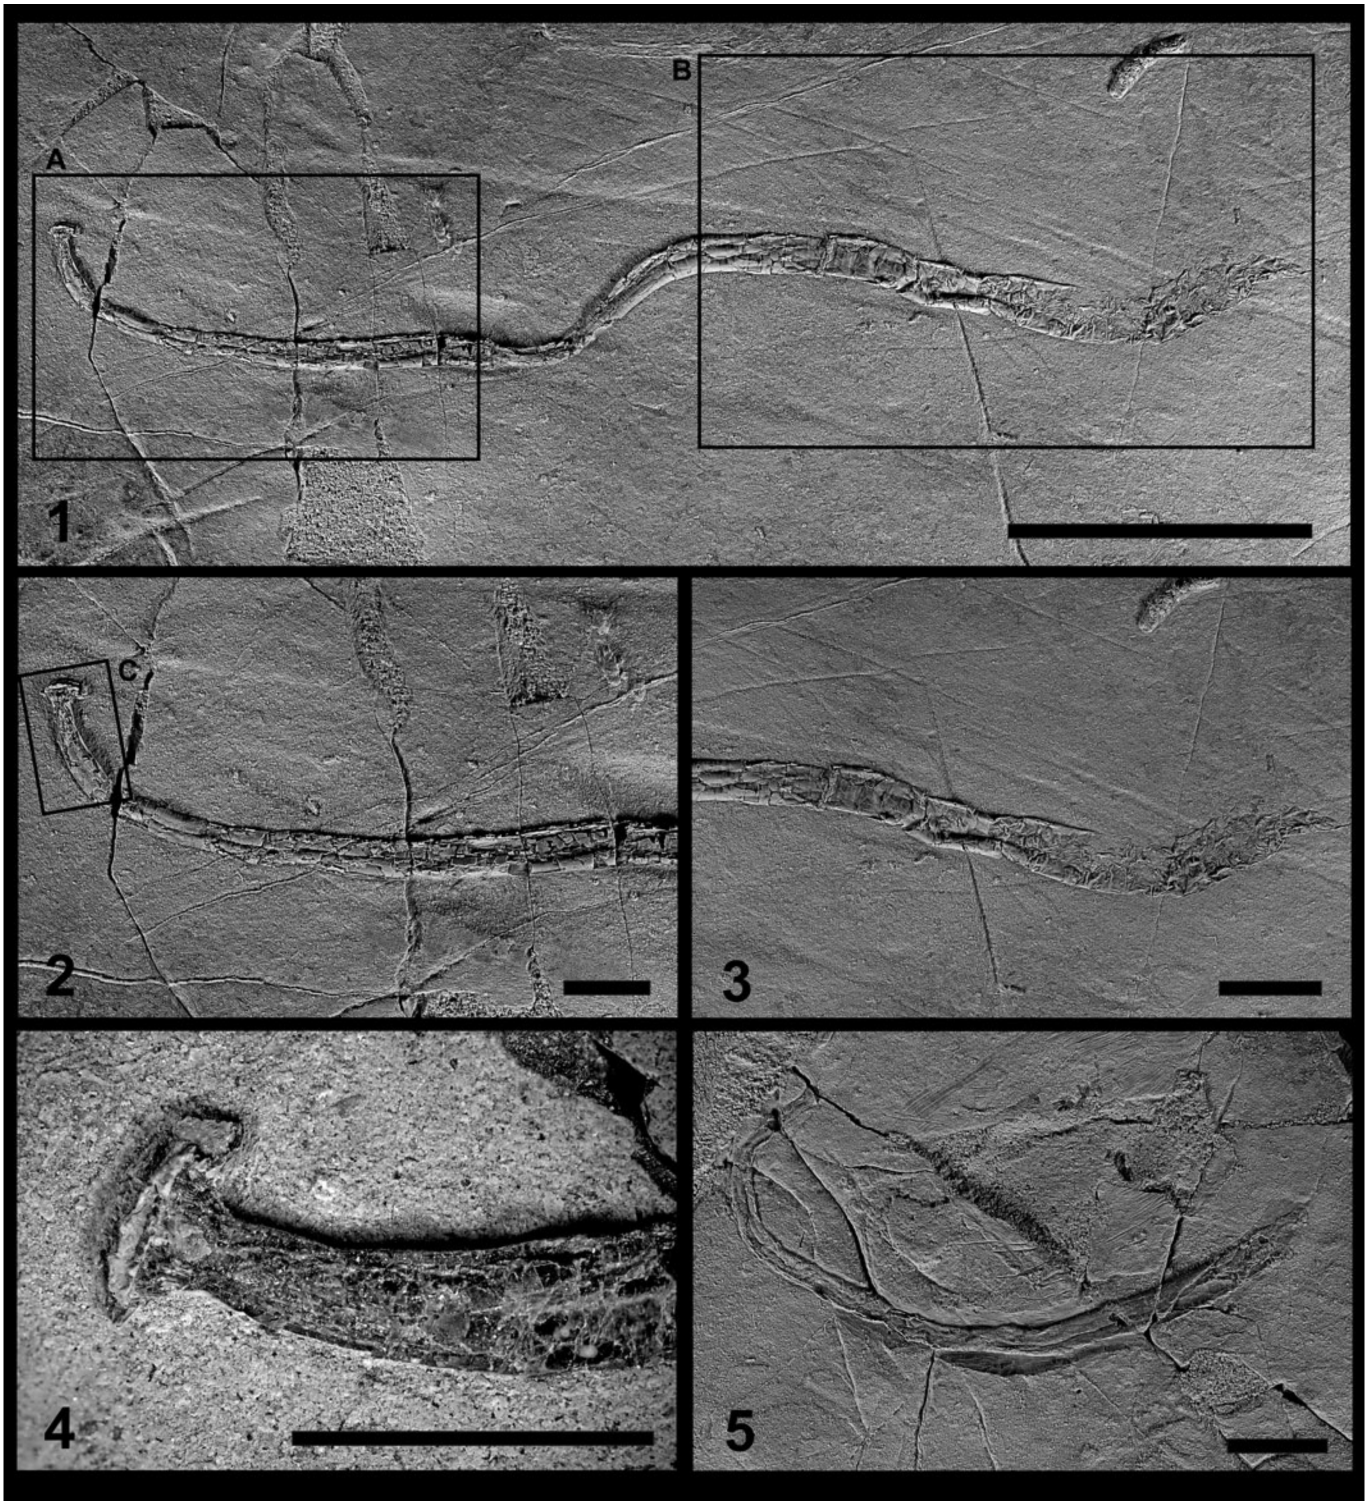

Figure 3. *Sphenothallus carniolica* (Kolar-Jurkovšek and Jurkovšek, 1997) from the Late Triassic (late Carnian) Kozja dnina Member of the Martuljek Limestone of northwest Slovenia (Vrata Valley). (**1–4**) BJ1286, the holotype and most complete specimen: (**1**) side view of the entire specimen, which preserves both the apical holdfast (left end of the specimen) and the apertural region of the main tube (right end of the specimen); (**2**) detail of the area in box (A) in (**1**), showing the apical region with berm-like marginal thickenings; (**3**) detail of the area in box (B) in (**1**), showing the heavily crumpled, relatively thin apertural region; (**4**) detail of the area in box (C) in (**2**), highlighting the sub-conical apical holdfast; (**5**) BJ1419, paratype, a nearly complete specimen with partially preserved apical holdfast. Scale bars = 30 mm (**1**) and 10 mm (**2–5**).

Additionally, since *Sphenothallus* has not yet been documented from any part of the Permian System, it may be a Lazarus taxon (Jablonski, 1986). Nevertheless, we predict that the existence of *Sphenothallus* of Permian age, previously only asserted, will be confirmed and that additional discoveries of Triassic and maybe even younger *Sphenothallus* will be made, based in part on the ability of *Sphenothallus* to survive the most severe crisis in the history of life during the Phanerozoic Eon. Finally, given the

presence of conulariids, which are commonly associated with *Sphenothallus*, in strata of terminal Ediacaran age (Van Iten et al., 2016b; Leme et al., 2022), we would not be surprised if the first appearance of *Sphenothallus* were extended downward into that system.

Acknowledgments

The authors are grateful to M. Miller (Geological Survey of Slovenia) for SEM photography and EDS analysis of *Sphenothallus* specimens and to the administration of the Triglav National Park for permission to perform paleontological research within its boundary. We also thank reviewers J.S. Peel (Department of Earth Sciences, Uppsala University, Sweden) and O. Vinn (Department of Geology, University of Tartu, Estonia) and associate editor R.J. Elias (Department of Earth Sciences, University of Manitoba, Winnipeg, Canada) for their constructive comments on and corrections of the original manuscript.
