

ON REDUCIBILITY OF TRINOMIALS

by ANDREW BREMNER

(Received 12 November, 1979)

In Schinzel [1] the following interesting question is asked: does there exist an absolute constant K such that every trinomial in $\mathbb{Q}[x]$ has a factor irreducible in $\mathbb{Q}[x]$ which has at most K terms? The only known result appears to be that of Mrs. H. Smyczek, given in the above paper, that if K exists, then $K \geq 6$. We here extend this bound to $K \geq 8$ by exhibiting a trinomial in $\mathbb{Z}[x]$ which splits into the product of two irreducible factors, each having 8 terms.

We consider for suitable integers a, b, c, d, e, f, g and prime p , the product

$$(x^7 + 2pax^6 + 2pbx^5 + 2pcx^4 + 2pdx^3 + 2pex^2 + 2pfx + pg) \times (x^7 - 2pax^6 + 2pbx^5 - 2pcx^4 + 2pdx^3 - 2pex^2 + 2pfx - pg) \quad (1)$$

where the two factors are \mathbb{Q} -irreducible by Eisenstein's criterion if $p \nmid g$. We automatically have that the coefficients of odd powers of x in the product are zero; and we impose restrictions on a, b, \dots, g by demanding that the coefficients of $x^{12}, x^{10}, \dots, x^4$ be also zero, so that the product (1) is indeed a trinomial, of the form $x^{14} + Ax^2 + B$.

This requires

$$\begin{aligned} b &= pa^2, \\ d &= pa(2c - p^2a^3), \\ f &= pc^2 + 2pae - 2p^3a^3(2c - p^2a^3), \\ g &= 6p^2ac^2 - 12p^4a^4c + 5p^6a^7 + 4p^2a^2e - \frac{2ce}{a}, \end{aligned}$$

and

$$e^2 - e\left(4p^2a^2c - 4p^4a^5 + \frac{2c^2}{a}\right) + (2p^2ac^3 + 6p^4a^4c^2 - 11p^6a^7c + 4p^8a^{10}) = 0.$$

The latter equation is just

$$e = 2p^2a^2c - 2p^4a^5 + \frac{c^2}{a} \pm D, \quad (2)$$

where

$$D^2 = \frac{1}{a^2} (c - p^2a^3)c(c^2 + 3p^2a^3c - 3p^4a^6);$$

equivalently,

$$Y^2 = X(X - 1)(X^2 + 3X - 3) \quad (3)$$

Glasgow Math. J. **22** (1981) 155–156.

with

$$Y = D/p^4 a^5, \quad X = c/p^2 a^3. \quad (4)$$

Now (3) is just the equation of an elliptic curve; if we transform by $s = Y/X^2$, and $t = 1 - (1/X)$, we obtain the curve

$$s^2 = t(1 + 3t - 3t^2), \quad (5)$$

and it is straightforward to show by standard methods that the group of rational points on (5) is generated by $(0, 0)$ of order 2 and $(1, 1)$ of infinite order.

Calculation gives

$$7(1, 1) = \left(\frac{16351^2}{28489^2}, \dots \right)$$

with corresponding value of X equal to

$$\frac{31^2 \cdot 919^2}{2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 17^2 \cdot 19 \cdot 59};$$

and we can thus see from (4) how to choose a , c , p —indeed we can take $p = 17$, $a = 2^2 \cdot 3 \cdot 5 \cdot 7 \cdot 19 \cdot 59$, $c = 2^2 \cdot 3^2 \cdot 5^2 \cdot 7^2 \cdot 19^2 \cdot 59^2 \cdot 31^2 \cdot 919^2$. Since $a \mid c$ all the coefficients are integers; and since $17 \nmid c^2/a$ we can ensure, by appropriate choice of sign for D in (2), that $17 \nmid e$, whence $17 \nmid g$ as required for applying the Eisenstein criterion. The remaining coefficients can now be calculated explicitly, but are rather large.
