# 36. A NEW INTERPRETATION OF THE GALACTIC STRUCTURE FROM Hii REGIONS 

G. COURTĖS, Y.P. and Y.M. GEORGELIN, and G. MONNET<br>Observatoire de Marseille, Laboratoire d'Astronomie Spatiale, Marseille, France

#### Abstract

From 6000 optical radial velocities of Hir regions a new spiral structure (4 arms of pitch angle $20^{\circ}$ ) is found. The radial velocities of the observed HII regions are the same with the velocities of the $H_{I}$ regions. The kinematics of $H_{\text {II }}$ regions is similar to that of Cepheids and B stars.

A number of radial velocities of $\mathrm{H}_{\text {II }}$ regions were first obtained by Courtès (1962, 1960); later Courtès et. al. (1968) collected 4000 optical radial velocities of $150 \mathrm{H}_{\text {II }}$ regions. Now, 6000 optical velocities have been measured and will be presented elsewhere (Georgelin, 1969). Figure 1 and Figures 2 and 4 of Courtès et al. (1969) show a comparison with recent surveys at 21 cm . There is a very close agreement between $\mathrm{H} \alpha$ velocities and the main maxima of the $21-\mathrm{cm}$ line (as found by Courtès in 1959). The position of the main body of each spiral arm is then well defined from the distances of the Hir regions. Those distances are, of course, those of the exciting stars which have been determined by spectrophotometric studies (Becker, 1963; Lyngå, 1964-65; Georgelin, 1969).

Radial velocities and spectrophotometric distances of $\mathrm{H}_{\text {II }}$ regions give a model of the rotation curve of the Galaxy which is identical to the Schmidt curve (Courtè et al., 1968). This agreement between the two rotation curves (Figure 5 of Courtès et al., 1969) indicates that Hir regions have the same rotational velocities as other population I components such as bright cepheids and neutral hydrogen. The constants of the solar motion $\left(U_{0}, V_{0}, W_{0}\right)$, of the galactic rotation $(A)$, and of the expansion ( $c$ and $k$ ) have been computed by the same method used by Kraft and Schmidt (1963) for the cepheids. The results of Georgelin (1969) are compared (Table 1 of Courtès et al., 1969) with those of Kraft and Schmidt (1963) for the cepheids and those of Feast and Shuttleworth (1965) for the B stars.

The conclusion of a pitch angle of $20^{\circ}$ (Courtès et al., 1968) is of course in contradiction with the nearly circular arms given by the classical $21-\mathrm{cm}$ model of Oort et al. (1958), but agrees with the details of the $21-\mathrm{cm}$ data themselves, and we feel that this shortcoming of the earlier model is due to a misinterpretation of $21-\mathrm{cm}$ data:

Kinematic distances inferred from $21-\mathrm{cm}$ radial velocities are correctly defined only at angular displacements greater than $20^{\circ}$ from the centre-anticentre direction. The existence of such an indeterminate sector leads to a fundamental ambiguity in the connection of the two fractions of each spiral arm across this sector. One can join, e.g., the Carina arm to the Cygnus arm (pitch angle $0^{\circ}-21 \mathrm{~cm}$ model) or to the Sagittarius arm (pitch angle $25^{\circ}$ - optical model). In four sectors only, the distance of spiral arms is well known from radial velocities. But the pitch angle can only be marginally defined because this sector is too short in longitude $\left(60^{\circ}\right)$ and the precision of the kinematic distances at the extremity of each sector which defines the inclination.

Fig. 1. Comparison between velocities of $\mathrm{H}_{\mathrm{I}}$ and HII regions. - Hi data from Kerr and Hindman (1966), Kerr (1969). His data from Courtè (1960) Cruvellier (1967) and Georgelin (1969).

Sagittarius-Carina arm. $\square$ Norma-Centaurus arm.

On the other hand, spectrophotometric distances for Hir regions can be used through the full longitude range. In particular, a clear morphological continuity is obtained for an inner spiral arm reaching from Carina to Sagittarius. Because of this linear continuity, the distance of this arm can also be obtained by the slope of the differential rotation curve in the longitude range $0^{\circ}-33^{\circ}$ (Cruvellier, 1967) and this distance agrees quite well with the photometric distances.

With this interpretation of $21-\mathrm{cm}$ data, no large discrepancy remains. In the 305$333^{\circ}$ range $21-\mathrm{cm}$ observations give a broad Hi distribution from 1 to 4 kpc which was interpreted differently by Oort et al. (1958) and Kerr and Westerhout (1965). On the other hand, HiI regions give a clear separation between two arms at respectively 1.5 and 3.5 kpc .

From those data, four spiral arms can then be drawn with confidence (Table I and Figure 2).

TABLE I
Data on the four nearest spiral arms

| Spiral arm | Longitude range ( ${ }^{11}$ ) | Distance | Remark |
| :---: | :---: | :---: | :---: |
| + I | $103^{\circ}-190^{\circ}$ | 3 kpc at $120^{\circ}$ | Very conspicuous |
| Perseus | Sharpless 132 Early type stars |  | Between $140^{\circ}$ and $168^{\circ}$ |
| 0 | $59^{\circ}-254^{\circ}$ | 0.5 kpc at $180^{\circ}$ | Quite poorly defined |
| Orion | NGC 6820 Rodgers 19 |  | The sun is located at the inner edge of the arm |
| - I | $274^{\circ}-32^{\circ}$ | 1.5 kpc at $330^{\circ}$ | Well defined |
| Sagittarius | Rodgers 42 Sharpless 69 |  |  |
| - II | $305^{\circ}-333^{\circ}$ | 3.5 kpc at $330^{\circ}$ | Clearly separated |
| Norma | Rodgers 74 Rodgers 106 |  | From the Sagittarius arm |

Fig. 2. Schematic sketch of galactic spiral arms.

It is particularly interesting that during this Symposium Dr. Weaver has presented a new interpretation of $21-\mathrm{cm}$ radial velocities, which seems to be in close agreement with the spiral structure presented above - and thus strengthens this result.

The details of this work will be published by Courtès and Georgelin in Vistas in Astronomy (1970).
